VARIETIES.—Twelve good varieties for dessert are Mrs. Gladstone, Irish Peach, Beauty of Bath, Worcester Pearmain, King of the Pippins, Blenheim Pippin, Wyken Pippin, Cox's Orange Pippin, Ribston Pippin, Cockle's Pippin, Claygate Pearmain, and Sturmer Pippin, ripening in the order named.

It is hard to single out twelve sorts and say they are the best cooking Apples, soil and climate having a wonderful influence on the size, colour, and flavour of some varieties. Lord Suffield, Domino, Ecklinville, Warner's King, Greenup's Pippin, Peasgood's Nonesuch, Mère de

Ménage, Lord Derby, The Queen, Bismarck, Alfriston, and Bramley's Seedling are all good.

Some varieties of Apples, like many other fruits, refuse to bear in one locality, and are most prolific in other places, all under good management. That the form of training and stock may influence the growing and fruiting I admit; but still some will not bear and others canker. The worst for canker, I find, are Ribston Pippin, Tom Putt, Cellini, Lord Derby, Lord Suffield, Bismarck, Alfriston, and Claygate Pearmain; those that crop the lightest are Gravenstein, Peasgood's Nonesuch, Blenheim Pippin, and Moulton Pippin.—W. T., Ireland.

FRUIT FORCING.

Cherry House.—Cherries are ripening rapidly in the house, brought forward gently from the early part of the year, and the fruit must be kept dry; but air moisture is necessary for the health of the trees, and may be secured by damping the border occasionally with the syringe, air being admitted constantly, or condensation will seriously affect the fruit. Sprinkling the border is apt to mislead as regards its condition, which at this stage must be kept moist, therefore if necessary a thorough supply of water must be afforded without delay. Tie in the shoots as they lengthen, and stop those not required for training at the fifth leaf. Black aphides can be kept under by dipping and rubbing the leaves or shoots in tobacco water. Ventilate freely on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to insure a circulation of warm dry air. Netting will be necessary over the ventilators to prevent birds attacking the Cherries.

Cucumbers.—Plants that have been in bearing all the winter will now be showing signs of exhaustion. Remove them, and after putting the house into a state of thorough cleanliness, taking out the old soil and introducing fresh compost, place out strong healthy young plants without delay. These will come into bearing quickly, and give abundance of fruit for some time. Assist young plants showing signs of weakness by removing the staminate flowers and the first fruits, stopping at every third or fourth joint; removing all weakly and surplus growths. Plants in bearing will require copious supplies of water and liquid manure or top-dressings of fertiliser washed in moderately. Extra vigour may be secured by employing a little nitrate of soda in the water, but not more than half-ounce to a gallon of water, besides it acts well against eelworm. It is better to mix the nitrate of soda with a small quantity of water, say 1 lb. to gallon, and let stand a short time, then add half pint of the solution to each 4 gallons of water employed for watering. This is only a quarter ounce of nitrate of soda to a gallon of water, but it gives excellent results in both quantity and colour of fruit.

Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially houses facing south, but shade early to prevent flagging. Houses with the roof lights facing east and west will not require shading. Little or no fire heat will be required by day, shutting off the valves at about 8 A.M., and opening them again at about 5 P.M. Syringe the plants moderately between 3 and 4 P.M., keeping a good moisture by damping the floors. If aphides appear fumigate on a calm evening and repeat early the following morning, having the foliage dry, but the floors well damped. On an attack of red spider remove the worst infested leaves, and syringe the plants with petroleum emulsion, 1 part in 50 parts water. Guano water, 1 lb. in 20 gallons of water, may be used occasionally in the evening to charge the atmosphere with ammonia vapour, or liquid manure from stables or cow houses, diluted with five or six times its bulk of water, may be used for the same purpose. Either may be applied to the roots about twice a week, the plants not being allowed to suffer through insufficient supplies of water and nourishment in available form. If mildew appear dust with flowers of sulphur, but its fumes from lightly coating the hot-water pipes are more fatal to it and effective also against red spider and white fly.

Seeds may be sown for raising plants to occupy pits and frames. A fair bottom heat should be secured by using the less decomposed material from Seakale, Vine borders, or exhausted hotbeds, which, with about a fourth of fresh material, will afford all the bottom heat now required. The nights lately have been cold, in which case close pits and frames as early in the afternoon as safe, not allowing the temperature to exceed 90°, 95°, or 100°, and afford good night coverings. See that a good top and bottom heat is maintained by duly renewing the linings.

Figs.—*Early Forced Trees in Pots.*—When the first crop on the very early varieties, such as Early Violet and St. John's, are gathered, return to the treatment applicable to trees swelling the crops. If red spider has gained a footing wash the leaves with a solution of soluble petroleum or emulsion, also the wood where there is any scale, dislodging it with a brush, syringing the trees forcibly on fine evenings until new growth is being made freely, ordinarily syringing twice a-day—in the morning and early afternoon. Where the second crop is thickly set

thin liberally, leaving the fruits near the base of the shoots, and to secure a full first crop another year be careful not to overtax the trees. Expose the fruit ripening as much as possible, and increase the ventilation. This will be the case with Brown Turkey—the finest of Figs for general purposes; and where its second crop is thickly set thin the fruits well, as there is no danger of the trees casting their fruits after this period if they are well attended to with water and nourishment. Stop the shoots and thin where crowded, for vigorous sturdy shoots produce the finest Figs.

Planted-out Trees.—The earliest started have the fruit approaching ripeness, and must not be wetted, maintaining atmospheric moisture by keeping the mulching, walls and paths, properly moistened. Moisture can be prevented from condensing on the fruit by maintaining a steady circulation of air, with gentle fire heat. Care must be taken to afford plentiful supplies of water and nutriment at the roots. When this is neglected the trees become infested with red spider, and as a natural consequence the ripening period is shortened, and the second crop is puny, rusty, and unsatisfactory. Allow the leading shoots to extend, unless unduly vigorous, without stopping until they reach the extremity of the trellis, then stop them, and cut away after fruiting to make room for succeeding fruitful wood.

Late Houses.—Excellent Figs are grown in unheated houses, producing one crop, which affords an acceptable supply of fruit in August and September. The trees are showing plenty of fruit. With the roots confined to moderate space within the house, the border concreted, and thoroughly drained with broken bricks and old lime rubbish, they should have very copious supplies of water, and be syringed twice a day. In cloudy weather, however, the afternoon syringing should be dispensed with, and in bright weather it may be performed early, with all the sun heat that can be shut in to insure the proper drying of the foliage before nightfall. The young growths in these structures should be trained a good distance apart, every growth having full exposure to light and air, so as to secure sturdy fruitful wood.

Melons.—The fruits always have flavour in degree of the solar heat, and the weather lately has been all that the early Melon grower desires. The days have been bright though the air has been cold, necessitating the employment of fires, especially at night, as it is a great mistake to allow too great a difference between the day and night temperatures. Maintain 70° as the minimum, though 65° or even 60° will do no harm when the nights are unusually cold and the days bright, 70° to 75° by day being secured artificially, admitting a little air at and above the latter, allowing an advance to 85° or 90°, and closing early so as to secure a temperature of 90° or 95° for some time. Keep plenty of atmospheric moisture in houses containing young growing plants or those swelling their fruit, gently damping the walls, floor, as well as foliage, and closing about 3.30 P.M., or as early as safe. Feed plants liberally that have their fruit swelling, not allowing them to suffer through insufficient supplies of water, and afford weak liquid manure or moderate top-dressings of fertilisers washed in. Fertilise all pistillate flowers daily, insuring a somewhat dry condition of the atmosphere, not using the knife during that period, but pinch out the points of the shoots at one or two joints beyond the fruit. Earth up plants that have set their fruits, and examine them frequently for the removal of superfluous growths, not allowing them to interfere with the principal foliage. Shade as little as possible, and only to prevent flagging.

When the fruit is cut from the earliest plants the old stem may be cut to a strong shoot near its base, removing as much of the old soil as can be picked out from amongst the roots, adding fresh in its place, rather lumpy, and well pressed down, giving a good watering. If a moist atmosphere is maintained, and the plants are syringed in the morning and about 4 P.M., they will soon start freely, showing fruit in much less time than by starting afresh. If they have healthy growths they need not be cut down so closely, but laterals taken at suitable distances, and the old shortened or cut away, the fresh laterals will show fruit at a few joints of growth. If, however, the plants are affected with canker, or from carrying too heavy crops at first, a deficiency of water, or attacks of insects are much enfeebled, it is better to remove them, thoroughly cleansing the house, placing strong plants in ridges or hillocks.

Plants in Pits and Frames.—Grand fruits are grown in these simple structures. The thing is to keep the fruit clear of the soil and fully exposed to the sun by raising them on inverted flower pots with a piece of slate intervening, as the moisture from the bed is apt to accumulate in the pot, and rising through the hole cause the fruit laid upon it to decay at that part. Admit air freely, and water only to prevent the foliage flagging. If a second crop is desired encourage about four shoots from each plant at the base of the stems now bearing, and when the fruit is cut the old growths may be removed and young shoots substituted. These will show fruit on the first laterals, every alternate lateral being rubbed off to prevent crowding. If a top-dressing of fresh compost is given the plants will be assisted to make a second growth.

A useful crop of Melons may be obtained by making up beds now of any spent material, which with mixing and turning will generate a gentle warmth, placing over it frames that have been used for Potatoes and bedding plants, and in each light a barrowful of any strong loam mixed with some old mortar rubbish or road scrapings if deficient in grit, pressing it down firmly; into this, when warmed through, turn out a strong healthy plant, pressing the soil firmly about the roots, and giving a good watering. If pits are employed the surface of the soil must be brought up to a foot from the glass and the materials firmed well, so as to prevent much settling. If the weather be bright shade

for a few days after planting. Seed may be sown to raise plants for frames at present occupied by tender bedding plants.

Pines.—Changeable weather necessitates careful attention in ventilating plants with fruits in an advanced condition, otherwise sudden outbursts of sun tell disastrously on the crowns. Admit air at the top of the house at 80°, and maintain the temperature through the day at 80° to 90°, closing at 85°; but unless it be desirable to enlarge the crowns do not quite close the house. Fire heat must be employed to prevent the temperature falling below 70° at night, and to raise it to 75° in the day, keeping the bottom heat steady at 80° to 90°. Syringe the plants two or three times a week according to the weather, and maintain the atmosphere in a genial condition, in order to secure the perfect development of the fruit.

THE KITCHEN GARDEN.

Runner Beans.—Early seed-sowing has not been a success in the case of retentive soils, and the plants have come up very irregularly on lighter warm ground. Cold winds and frosts have retarded growth considerably, and in some instances it will be found the best plan to sow more seed at once. These Beans transplant readily, and if there are enough plants in two rows to form one good one that is what should be done with them. There would also be a gain of a week or more in sowing in small pots singly, or in boxes thinly under glass and in gentle heat, hardening and planting before the plants become matted together at the roots. Thinly grown plants give the best results, those much crowded cropping lightly, being also the first to fail in a dry season. One strong plant to each pole or stake is sufficient, and these may well be a foot apart, bracing and supporting each other by means of a stake running along near the tops of the poles. Continue to shelter and protect during cold nights. Now is a good time to sow seed in quantity with a view to having rows or breadths capable of yielding pods in abundance till the end of the season. What these Beans require is a deep, rich, freely worked root run, wholly trenching the ground answering better than merely digging Celery-like trenches, the sides of which are apt to shrink away from the soil in the trench, and in a hard and dry state prevent the free spread of roots.

Runner Beans Without Stakes.—The bulk of Beans sent to the markets during the season are grown in the open fields without the aid of stakes, and the market growers' plan may also be adopted in all cases where stakes are difficult to procure. If they fail it will most probably be due to want of attention in topping, which must be done persistently, and in mulching with strawy manure to keep the ground moist and the crops clean. Sow the seeds thinly in single drills 3 feet apart, eventually thinning out the plants to a distance of 12 inches asunder.

Cropping Between the Rows.—Where close cropping is practised the spaces between the rows of Runner Beans ought always to be utilised during the early part of the season. Short-topped early maturing Potatoes may yet be planted, arranging for two or more rows in the 6 feet or wider widths, and one row between those to be topped. The Potato crops will be fit for lifting before the Beans shade the ground heavily. Lettuces, Turnips, or other quick-growing crops may also be grown between Runner Beans.

Ridge Cucumbers.—These succeed well in open positions with a slope to the south, always provided they are sheltered from cold winds in May and June, and a fair amount of sunshine reaches them. In cold sunless summers they do not pay for the trouble taken with them, not even if grown on heaps of decaying manure. For a few plants a ridge or bed of decaying manure, weeds, leaves, grass from the mowing machine, and the like may be formed in a sheltered corner in the frame ground, making this from 2 feet to 3 feet deep, and wide or square rather than narrow, narrow ridges being the first to become cold, and to suffer from drought. On these beds form mounds of good light loamy compost 3 feet apart each way. When the soil is warmed through either sow four or five seeds in each mound, or plant out from small pots, taking care to do this before the plants become starved and yellow in appearance. Shelter with either hand-lights, large bell-glasses, inverted flower pots, old handleless baskets, or other contrivances, and peg down the plants to prevent injury from the winds in the daytime. For culture on a large scale see Vegetable Marrows.

Vegetable Marrows.—These are indispensable. When we experience hot and dry summers Vegetable Marrows are not unfrequently the only green vegetable available in large quantities, and that, too, without any special efforts on the part of cultivators. In small gardens they are principally grown on beds or ridges of manure and soil, much as advised in the case of ridge Cucumbers; but when the market growers' plan is adopted much less haulm forms and far heavier crops are obtained. For an early supply these mild hotbeds and either frames or hand-lights are of good service in giving the plants a strong start, allowing the haulm to ramble naturally when it begins to get crowded. In addition to these a few or many plants may well be grown in the open garden. Select a sunny spot, sloping to the south or in a southerly direction, and mark out a width of 4 feet. Prepare by throwing out the best of the top spit of soil to a depth of 12 inches, next wheeling into the trench thus formed a solid foot of partially decayed manure, distributing the soil just thrown out over the sides and on the top of this. The heat in the manure coupled with sunshine will soon warm the soil through, and it is then ready for the reception of either seeds or plants raised in pots under glass. One plant to every 3 feet run of bed is enough, but two or three seeds should be sown at every site, leaving the strongest plant resulting and early removing the rest. Protect plants from cold winds and late frosts, much as advised in the case of ridge Cucumbers.

Weeds.—The long spell of cold, wet weather that has greatly checked the progress of most crops has not had a similar effect upon weeds, and they are in the ascendant accordingly. Advantage should be taken of fine, clear days to frequently hoe among all advancing crops, well stirring the surface, and at the same time destroying the weeds.

THE BEE-KEEPER.

SEASONABLE FLOWERS FOR BEES.

A FEW fine days and a higher temperature have had the desired effect in the apiary. Here all is life and bustle where a few days before only a solitary bee, more venturesome than the others, was to be seen on the wing. Now they are returning home in their thousands, heavily laden with pollen, and doubtless with a little honey; so eager are they to gain the entrance to their hive that many fail in the first attempt, the large pellets of pollen with which they are loaded appearing almost too heavy for them. If the weather is fine they invariably rise again. It is the sudden showers that are prevalent at this season that dash them to the ground, many of them never to rise again.

But from what source do the bees obtain a supply of pollen and honey in the early days of May? In many country districts the plants, shrubs, and trees that are fast bursting into bloom are so numerous that it would seem almost impossible to name them all; a few of the more prominent, however, may be mentioned for the benefit of bee keepers.

In this district (South Yorkshire) the Wild Cherry trees, which are very plentiful in the woods, have been a sheet of bloom for at least a fortnight, and are much appreciated by the bees. They have also the advantage of being ornamental in the landscape at any season. The sweet or cultivated Cherry is equally good for the bees. Pears and Plums are now a mass of bloom, and bee-keepers will not need reminding of the benefits derived from bees in fertilising the flowers.

Bees obtained little benefit from the Gooseberries owing to the dull cold weather that prevailed during the time they were in bloom. The Sycamore and several varieties of Maple are fast opening their flowers and will soon be a mass of bloom. These are much frequented by bees, the former yielding a great quantity of honey when the weather is favourable. In the garden the white Arabis alba has been a sheet of bloom for several weeks past. Bees never appear to tire of working on this variety, owing to the fact of there being but few other flowers at the season when it first opens. In sheltered positions Tulips, Aubrietias, and Wallflowers will yield a wealth of bloom, the latter being much sought after by the bees, as a plentiful supply of pollen is obtained, and also honey when the weather is favourable. The fields, hedgerows, and woods are carpeted with flowers, many of which are of great benefit to the bees. These are more plentiful than usual, owing probably to the spell of dry weather experienced last summer and the excessive rainfall since.

REMOVING SPARE COMBS.

If not already done it will be an advantage to remove all spare combs not covered by the bees. If the stocks are examined in the afternoon of a warm day it will at once be seen how many combs are required. By removing the outside frames and closing the division board up to those remaining in the hive the space will be contracted, and will be the means of maintaining a higher temperature in the hive than would otherwise be the case.

The spare combs can be returned to the stock as required. If the colony is a strong one an empty frame may be given every three or four days. Should a hive become crowded with bees and little honey is coming in, a frame of sealed-up brood may be taken out and given to a weak colony. Shake all the adult bees off; many young ones will adhere to the comb, which may be allowed to remain to strengthen the weak stock; being young they will not fight, and the weaker colony will accept them joyfully. This shows the advantage of having all frames the same size in an apiary.

SPREADING BROOD.

Is it advisable to spread brood with a view to strengthening a colony? is a question that is often asked. Personally, I may say I am not in favour of it, although I have often practised it in days gone by, for the simple reason that others did it, and as it was all the rage many years ago amongst advanced bee-keepers, or rather those who tried to improve on Nature. But what is spreading brood? someone may ask. It is this. When the weather is fairly warm in the spring, say the beginning of May, contract the hive, only leave in as many frames as are well covered by the bees. A

few days after, when the cells are all filled with eggs and brood, insert another frame of foundation, or, better still, fully drawn out worker comb, in the centre of the brood nest, repeating this as often as is necessary. The plan answers admirably if one could only rely on the weather being warm, but such is not the case for many days together in this country. If the days are bright there is often a frost at night, and the bees cluster in the centre of brood nest, with the consequence that the brood in the outside combs becomes chilled, and instead of the colony being strengthened it has quite the opposite effect. Spreading brood has done much harm to modern bee-keeping, and as it requires so much care and judgment I do not recommend its adoption.

I prefer the more rational system of placing the empty comb between the outside comb containing stores and the next one which the queen has filled with eggs and brood. Do this as often as necessary, and there will be no fear of having chilled brood and its attending evils. When empty frames are being given to stocks, if honey is not coming in freely it will be an advantage to uncap some of the sealed up stores, this will encourage the queen to continue laying.—AN ENGLISH BEE-KEEPER.

* * All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Educational (J. H. D.).—If the evidence in our possession is not misleading, and we do not think it is, the Institution in question is at present without the requisite means for meeting your anticipations, and you will probably act wisely by waiting the issue of events, which may possibly be of a favourable character.

Insects in American Wonder Peas (Wonder).—The insects in the Peas are the Pea-seed beetle (*Bruchus pisi*), which by its grubs feeding in the Peas lessens their weight and value for seed, as where the substance of the Peas is much eaten away the growing power of the young plant from the damaged seed is also much lessened. Peas infested by the beetle are easily distinguished by having a little round depression in the skin, which is slightly yellowish or transparent, and caused by the substance of the Pea having been eaten away inside by the grub. It is hardly necessary to say that infested seed is not desirable for sowing, as the growth of this depends on the stored matter in the seed, and the first growth not being vigorous the later will be correspondingly stunted or sickly; but by treating both Beans and Peas before sowing with petroleum we have obtained satisfactory results. The Peas were placed in a flower pot with the hole corked and petroleum sprinkled on them, then by moving the Peas up and down by a throw-up and turn-over movement, effected by holding the flower pot by the rim with both hands, the seed was thoroughly moistened with the petroleum, and after draining off the superfluous oil the Peas sown. The petroleum sinks through the thin skin of the seed, where the beetle lies in the channel beneath. As to the beetles in the infested Peas being "likely to leave any progeny to develop this season," it is certain that the beetles would not be injured by being buried in the soil, for they require a certain amount of moisture, otherwise they die even in the seed. The beetles can be deterred from depositing their eggs on the embryonic pods by spraying the plants when showing blossom with a solution of soluble petroleum, which has also the advantage of preventing attacks of mildew and other pests. It should be applied in a dry time, or if wet repeating occasionally.

Overtime (Primrose).—You have evidently laboured diligently and done your best to write poetry on this prosaic subject, and succeeded in failing. In making engagements it is desirable to have a clear understanding on the subject of compensation for extra hours of labour, for the avoidance of subsequent disappointment.

Vine Leaves (J. D.).—It is quite common for parcels to be delivered some hours later in London than are letters posted at the same time. Your letter has been received, but not the parcel, though it perhaps might have been if you had addressed it as has been advised in our columns during the past three weeks. See instructions at the head of this page.

Cherry Tree Blossom Falling Off (J. M. H.).—The tiny grubs eating the embryo fruit are the larvæ or caterpillars of the winter moth (*Cheimatobia brumata*). There are also swarms of thrips, both larvæ, white or yellowish, and perfect forms, black—Thrips minutissima or vulgatissima. The surest means of destroying the caterpillar is to spray the trees with a mixture of Paris green, using the paste form, 1 oz. to 20 gallons of water, whilst the foliage is very young and tender also the caterpillars very small. The mixture must be applied by a spraying apparatus, such as the knapsack pump advertised in our columns, merely wetting the trees with the finest possible film of the mixture, and repeating at intervals of about four days or once a week for a time. If the caterpillars gain on the trees use it stronger, 1 oz. to 15 gallons of water, as the foliage will bear more and the caterpillars take more killing as the first gets firmer and the latter stronger. If you add 1½ oz. of softsoap to each gallon of the spraying mixture it will also kill the thrips. Killmright and other advertised insecticides act well against both caterpillars and thrips.

Diseased Vine Roots and Leaves (S. H., I. W.).—1, The malformed leaves from the Black Hamburgh Vines are crumpled in the middle next the footstalk, and appear to have had moisture resting there when the sun has acted powerfully upon them or air admitted so as to evaporate it rapidly; but there is no rust or scorching such as generally results therefrom, and no gnawing of the leaf surface such as occurs by infestation from Vine moth caterpillar. There also was no web, so we cannot make out anything but the moisture on the leaves as the likely cause. 2, The roots of the Black Alicante Vines are a similar enigma, for there are no fungus or micro-organism of any kind; but they are simply dead, and the loss of the roots is probably the cause of the shoots becoming black at the tips. It is a case similar to "browning," but more decisive. There was no fungoid or other diseases so far as we could discover, and we consider the defective nature of the roots sufficient to account for the disease, which is not of an organic nature, but due to root destruction occasioned by sourness of the soil. Perhaps a dressing of best chalk lime, air slaked, would correct the sourness of the soil; at any rate it would not do any harm, and you may use it at the rate of 1½ cwt. per rod (30½ square yards) without any detriment, pointing in as deeply as can be done without injuring the roots. If these are near the surface let the lime remain on the top, and if you do not mind the appearance, a quarter of an inch thick of lime would not do any harm left on the border, and out of this sufficient in soluble form would pass into the soil to rectify its sourness, while it would the sooner become carbonated or revert to carbonate of lime.

Double Scarlet "Geraniums" for Market (W. B.).—You will find F. V. Raspail the most profitable, this variety flowering continuously all through the winter. Turtle's Surprise is good as a small pot plant for the markets, but it is not nearly so robust as the popular "Raspail." Strong young plants in 8-inch pots produce the finest trusses. Old stock plants, favoured by some of the growers in the London districts, flower more profusely, but the trusses are small, requiring more to make a saleable bunch. No gumming is needed. White-flowering varieties should also be tried. Hermine and Madame Rozain can be recommended; these, if not quite so floriferous as Raspails, yet pay well, especially where there is a local demand for white flowers. Sixpence per dozen trusses wholesale is a fair price for the scarlets, but the whites, if good, frequently fetch ninepence. Not later than March insert firm cuttings (young tops) either singly in thumb pots, or three or four round the sides of 4-inch pots. They will root readily in a brisk dry heat. When well rooted place the plants singly in 4-inch pots, and arrange them on staging not far from the glass in gentle heat. They may be topped either shortly before or soon after potting, and should be kept cleared of flower buds. Light frames are the best for them in May, and before they come root-bound the final shift should be given. The strongest and best plants may have 8-inch, and the rest 6-inch or 7-inch pots. Drain carefully and pot firmly, using a compost of two parts fibrous or good yellow loam to one of leaf soil, with a sprinkling of bonemeal and sand added. If frame room is limited arrange the plants in a sunny open position on a bed of ashes, but they are less liable to suffer from over-watering when kept a few days longer under glass. During the summer top often enough to form well balanced heads, also pinch off all flower trusses that form. Avoid undue crowding, and turn the plants round occasionally to prevent their rooting into the ashes. House before they are injured by cold wet weather. Arrange in light structures, raising them well up to the glass, either on temporary trellising or inverted flower pots. They require a dry heat, from 50° to 55° by night, with a slight increase on sunny days. In stronger heat and a moist atmosphere they grow too strongly and do not flower freely. Weak liquid manure may be given with advantage when the plants show signs of requiring it. The season lasts from October till Whitsuntide, after which bushy plants will frequently realise 9d. each for lawn and vase decoration.

Destroying Vegetation in Water Tanks (Telmah).—Chloride of lime would be likely to answer your purpose, adding 1 oz. to each gallon of the liquid in the tanks that may not be cleaned out. Crude carbolic acid, 1 oz. to a gallon of the liquid would serve the same object, or carbolic acid, No. 5 quality, one part to ninety-six parts = 1 gill (quarter pint) carbolic acid to 3 gallons of the liquid. We do not know of anything better, and though you say, "It does not matter about using a poison," we may direct attention to the poisonous nature of the substances named, and the danger of the water if partaken of by useful animals; while injury might follow the regular use of such water for watering plants. If there be any danger in using the poison the only course that can be safely followed is cleaning out the tanks.

Root of Lamb Mint Diseased (Mater).—The root is infested by the Mint smother fungus, *Helotium scutula*, or to be exact the form of it known as *H. s. menthae*. The procedure we should advise as the best means of getting rid of the fungus, is to break up the old beds, dry the stubble and roots, and burning them similar to couch grass. The fresh beds should be made in the early spring, when the young shoots are a few inches high, placing them in rows about 9 inches apart, and leaving out every sixth row so as to form beds. It is advisable to make fresh beds about every third year, or make new ones every year; and after the old beds have been hard cut for a time dig them, thus there will be a full supply of Mint, and the beds not more than three years old. You may sprinkle a little air-slaked lime on the infested bed, and this will destroy the fungus. About a peck of lime is sufficient for a rod of ground (30½ square yards).

Cut Flowers for Profit (A Beginner).—Not much can be done with one small greenhouse, though it ought to be found of considerable assistance in raising plants for growing in the "large garden." Much depends upon whether you expect to find a good local sale or not. Locally a greater variety will frequently sell readily than can be sent profitably to the markets. For the greenhouse prepare as many Chrysanthemums in pots as you can find room for, and as white flowers are most in demand let the selections of these, and other plants grown, consist principally of white. When the Chrysanthemums are over introduce Tea Roses in pots, and with these may be associated Hyacinths, Tulips, Narcissi, Spræas, and Gladioli. Tomatoes will be found the best summer crop. In the garden grow *Doronicums*, *Coreopsis lanceolata*, *Campanula persicifolia flore-pleno*, *Gypsophila paniculata*, *Ranunculus aconitifolius plenus*, *Rudbeckia Newmanni*, *Lilium candidum*, herbaceous Su flowers, *Anemone japonica alba*, *Pyrethrum niginosum*, dwarf *Pyrethrums*, early flowering Chrysanthemums, Roses, Carnations, Pinks, Mignonette, Violets, Wallflowers, Sweet Peas, Asters, Stocks, Zinnias, red, white, and yellow Cactus Dahlias, and white Antirrhinums. A few more kinds could be named as being suitable for your purpose, but we have given you enough to start with.

Ornithogalum Diseased (Gomersis).—The "shaw" or "grass" of the *Ornithogalum* bulbs is quite black, but on neither the bulbs nor the blades on the soil is there an affection of any kind. The epidermis of the leaves is ruptured more or less down to the soil, and bear fruits of the fungus, causing the black appearance of the "shaw." The parasite is the *Ornithogalum* black mould fungus, *Heterosporium ornithogali*, *Klotzsch* (syn. *Helminthosporium exasperatum Berk. and Br.*). The best preventive and remedy is spraying or sprinkling with a solution of permanganate of potash, 1 oz. to a gallon of soft water, or Condy's fluid diluted to a rose-coloured solution is simple and safe. A large tablespoonful to a quart of water suffices, and either the green or red fluid may be used. This will destroy the basal aggregation of hyphal cells, which is very important. It would be an excellent plan to transplant the bulbs into entirely fresh ground, as they seem much overcrowded, affording light yet good soil, with ample drainage. We should, however, treat the plants and place where they are growing with permanganate of potash solution as before advised. This cannot bring back health to the present leaves, as the disease is too deep rooted, but will do good.

Blistered Louise Bonne of Jersey Pear Fruit, Shoots, and Leaves (S. K.).—The young fruit and shoots, with the leaves, are affected by the Pear-leaf blister fungus, *Ascomyces bullatus, Berk.*, and also by the Pear-leaf gall mite, *Phytoptus pyri*, the latter being the more decisive. The fungus is accountable for the dying back of the young shoots, its mycelium being perennial in the wood, and in the spring spreads through the intercellular spaces of the tissues of the young shoots of infested plants. The tufts are at first small and isolated, but soon run into each other, and covered at first by the epidermis, which is raised in blisters, bright red in colour, with here and there prostrate hyphae appearing on the surface, once called *Actinonema crategi* or *Oidium bullatum*. The disease is spread by spores. These have not yet appeared; therefore, to act against both the fungus and mites, the tree may be sprayed or syringed, preferably the former, with a solution of soluble petroleum made as follows:—Dissolve 5 ozs. softsoap in a quart of water by boiling, and when dissolved remove from the fire for safety; then add a wineglassful of petroleum, stirring briskly till amalgamated, when dilute to 2½ to 3 gallons by adding sufficient hot water, and then cooled to 90° to 100° apply with a spraying apparatus or syringe, wetting the tree thoroughly on a calm afternoon after the sun is off. This may be repeated once or twice at intervals of about ten days. To reach the mites it is necessary to wet the under side of the leaves. If the young growths are affected by the mites about midsummer repeat the syringing at the early part of July. Another season spray or syringe the trees with soluble petroleum solution when the buds commence swelling, but before they burst, and it is likely you will not be troubled with the mites or even the fungus if you cut away the parts affected and burn them.

May-flowering Tulips (Mrs. H. F. F.).—Your beautiful yellow Tulip is *retroflexa*, of which bulbs should be ordered in September and planted when they are received. A charming companion to it is the variety called *Picotee*, while for richness in beds and borders *macrospila* cannot be easily surpassed. For colours see notes on Tulips, page 412.

Fuchsia Leaves Failing (G. B.).—The cause of the evil is mismanagement. By the pressing down of the soil after the roots had taken possession of it these may have been injured, and besides, the soil has been kept much too wet and sodden. Exercise more judgment in watering, keep the plant in a shady place for a week or more, sprinkle it occasionally, and maintain a rather damp atmosphere. So long as the soil feels pasty when rubbed give no water, but when it crumbles when pressed afford a supply.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (*E. E. C.*).—1, *Berberis Darwini*; 2, *B. stenophylla*. (*H. M. B.*).—1, *Tulipa sylvestris*; 2, *Doronicum plantagineum*, var.; 3, Dutch Tulip, *La Candeur*; 4, dead. (*S. G. T.*).—1, *Adiantum cuneatum*; 2, *A. gracilimum*; 3, *A. grandiceps*; 4, *Pteris tremula*; 5, specimen insufficient, send fertile frond; 6, *Pteris serrulata*. (*A. S. H.*).—1, *Cypripedium Lawrenceanum*; 2, *Lycaste Skinneri*; 3, a *Dendrobium*, but the specimen was too withered for specific identification. (*L. W. E.*).—1, *Prunus nana*; 2, *Magnolia Soulangeana*; 3, dead. (*G. P.*).—Your *nom de plume* is a word puzzle, and we give it up. If you read the above instructions you will perceive that flowering specimens are necessary for purposes of identification. 1, *Prunus padus*; 5, *Saxifraga muscosa*; 6, *Ribes aureum*; 2 appears to be a *Tiarella*, and 3 a *Heuchera*.

KETLOCKS.

YES, you may look in your dictionaries; it may be in some, but certainly is not in all, and the south country man will probably puzzle himself in vain. Well, for the benefit of all we will give other and possibly more familiar names.

Charlock or Cherlock, and Wild Mustard. It is a weed belonging to the cruciferous tribe, and its botanical name is *Sinapis arvensis*. It is an annual, with leaves toothed, and rough pods of many angles—rugged, longer than the awl-shaped beak; the seed is round and black, and being of an oily nature may lie for years in the soil unsuspected, and then, under favourable conditions, break forth into life.

That the Charlock is a true pest to both corn grower and root cultivator is a fact that admits of no doubt. The burning question is, how to get rid of it permanently. The seed being, as we before said, of an oily nature, it can remain buried in the ground for a great length of time without taking any harm. An extra deep ploughing may bring up to the surface thousands of seeds, which only need favourable conditions to spring into growth. Hardy as Ketlock is, it cannot stand frost, so that we seldom see it in winter-sown corn.

When Ketlock appears among the Turnip and Swede rows a timely hoeing prevents further mischief; it feeds and grows on the superphosphates, and in a dry time unless carefully watched will overpower the weaker growths of the roots. Like many other seeds Ketlock germinates most freely where the ground is well tilled, hence we see it so often abundantly in the beautifully prepared Barley lands. If it were always possible to get the Ketlock crop off first before sowing Barley all might be well, but as it is a matter of such vast importance to get Barley in early if you mean a really good crop precious time and opportunity cannot be wasted. Even should a crop of Ketlock be taken first you have no guarantee that there may not yet be more seeds that will still germinate. In a dry season, too, the less the land is worked after being thoroughly prepared the better. Every working means loss of moisture, and loss of moisture means slow growth, or perhaps no growth at all.

There are other means by which a field that is impregnated with this pest may be got clean. If the plant be removed before seeding the root of the matter is reached (we do not intend a pun). A fodder crop which is mown or eaten early will give the Ketlock plant no chance to propagate itself, nor will it have much chance among Potato tops or in well-weeded Swedes or Turnips. Of course it throws things out of gear on the farm to alter the rotation of crops, but nowadays we are more ready to diverge from the beaten paths than were our forefathers.

What is to be done, however, when these wretched weeds spring up in battalions among new sown corn? If seeds (Clover or Sainfoin) are not already sown the harrow is the only course open. Should seeds have been sown the harrow is out of the question. A suggestion has been made that in a case where the corn was badly infested with Ketlock to let both grow together till the latter was in flower, then mow and make hay. There would be a good mow, at any rate, and sheep relish Ketlock. The weed would be put beyond any chance of seeding.

Sheep, too, might be pastured on the weed-infested Barley, and should seeds have been sown in all probability the eating of the Barley would make the Clover plant come stronger. In any case folding with sheep would make a good preparation for an early sown Wheat plant in the autumn.

The old fashioned idea of boys and women pulling the obnoxious weed seems quite out of date. This possibly for several reasons—

firstly the expense, secondly the difficulty of finding the women and boys. In most country districts it is very rarely that you see a woman engaged in agricultural work. In Holderness they used to do most of the Wheat hoeing. Now, unless it is among Potatoes, they are conspicuous by their absence. As for the children, well, this higher education is at the root of their absence. They are learning something useful in the schools, but they are missing much that would be useful to them in after life, and the farmer in vain looks for some implement that would be equally efficacious as the little lads were when they went "ketlocking."

WORK ON THE HOME FARM.

There is little to chronicle this week that is of special interest. We have had a cold dry week, and vegetation has made small progress. The later sown Barley has come up quickly, and looks very well indeed, much better than that put in very early, which has had a sharp check. The forward Wheats, too, are yellow, and being overtaken by the later sown plots.

Many people have not got their Mangold in yet, and this crop may be reckoned as being fully a fortnight later than usual. When delay in sowing is unavoidable, it is better to have the seed well steeped before drilling; we have sown Mangold seed with very visible sprouts, and never had a better plant than on that occasion.

Carrots at £4 per ton are encouraging to the grower, and in Carrot districts the drill is hard at work. Eight lbs. per acre are drilled about 20 inches wide. Intermediate and Stump-rooted are the varieties most in favour.

Our first foal has safely arrived after a few nights anxious watching. An unfal mare should be seen every half-hour as foaling draws near, a few minutes longer may easily mean the loss of a valuable foal.

The cattle are all out and looking well, but there is little grass visible; unless we have some warm weather shortly there must be a scarcity of keep. Seeds are very bare; they are too thinly planted to carry much stock.

Fallows are ready for Turnips as regards cleanliness, but not as regards tilth; many fields are decidedly rough. The dry weather is drying the clods, and only a good steeping rain is required to produce a good seed bed.

Potatoes which have not been ridge-harrowed should be attended to at once, as the young sprouts will soon appear and are easily broken off. If there is danger of this the middle teeth of the harrow are better removed temporarily. It is good policy to get the Potatoes cleaned as early as possible. Much harm may be done, particularly to early sorts, by disturbing the young roots after tubers have begun to form.

This promises to be a great year for Thistles, perhaps the result of a wet autumn and consequent absence of autumn dressings; but this does not apply to the Wheat crop, which is now much in need of weeding. Hoeing has gone out of fashion, but should be practised this year, Wheat being thin on the ground and as a consequence very much threatened with weed competition.

Journal of Horticulture.

THURSDAY, MAY 20, 1897.

FOOD REQUIREMENTS OF TOMATOES.

THE growing of Tomato plants to produce fruit for market has during the past few years developed into a very important industry. To some growers the culture of these plants is quite an easy matter, for they seem to be able to grow good plants, free from disease, which produce abundance of fruit without any particular attention, while others, paying every attention to cultural details, cannot grow satisfactory crops. It may be that the soil and surroundings are more suitable in the former case; be that as it may, the facts remain the same.

In the following notes I do not propose to give cultural directions as to soil, watering, and tying, for they have already been fully dealt with in the *Journal of Horticulture* since the commencement of the present year, but wish rather to state the food requirements of the Tomato plant, and show how and in what form these may be applied.

In trying to determine what constituents the Tomato plant and its fruit require from the soil we must first of all know of what they consist. A fully developed Tomato plant—i.e., leaves and stem, when about 4 feet in height, will weigh 3 lbs. The root system to such a plant when free from soil will weigh 4 ozs., and such a plant on an average would produce 3 lbs. of fruit. This gives us a basis to work upon, and, together with a careful consideration of the analysis of the Tomato plant, its roots and fruit, will teach us what ingredients are required. The following analysis shows the most important constituents found in the fresh Tomato plant, its roots and fruit:—

TOMATO ANALYSIS.

SELECTED CONSTITUENTS IN	PLANTS	ROOTS	FRUIT
Nitrogen	0.32	0.24	0.16
Potash	0.45	0.34	0.25
Phosphoric acid	0.69	0.01	0.15
Lime	0.30	0.54	0.09

The above tables are very interesting, and much may be learnt from them valuable to cultivators. A careful study of them shows that the fresh plant contains about the same amount of nitrogen and lime, half as much again of potash, and more than twice as much phosphoric acid.

Passing from the plant to its roots, we find they contain more potash than nitrogen, scarcely any phosphoric acid, but a very large amount of lime.

The fruit of the Tomato only contains about half as much nitrogen and potash as the plant, less than a quarter as much phosphoric acid, and scarcely any lime.

What does this teach us? First of all that there must be an abundant supply of phosphoric acid and potash, and a fair proportion of nitrogen and lime, during the development of the plants; secondly, that the roots require a fair proportion of nitrogen and potash, and a large quantity of lime; and thirdly, that nitrogen, potash, and phosphoric acid are required in fair proportions for the development of the fruit.

Let us carry our inquiry a little farther, and see how much of these selected constituents a plant requires. The quantity of food needed by an individual plant is very small, and the weight of the different ingredients would have to be described in grains; we will, therefore, take 100 plants, this being a better number for the purpose of illustration.

One hundred Tomato plants, when 4 feet in height, would weigh about 300 lbs., the roots 400 ozs., and the fruit 300 lbs., and would contain, according to the above analysis, as follows:—

PLANTS—15½ ozs. of nitrogen, 1 lb. 6 ozs. of potash, 2 lbs. of phosphoric acid, and 15 ozs. of lime.

ROOTS—1 oz. of nitrogen, 1½ oz. of potash, traces of phosphoric acid, and 2¼ ozs. of lime.

FRUIT—8 ozs. of nitrogen, 12 ozs. of potash, 8 ozs. of phosphoric acid, and 4 ozs. of lime.

One hundred Tomato plants with their roots and fruit would, therefore, contain:—1 lb. 9 ozs. of nitrogen, equal to 11 lbs. of nitrate of soda; 1 lb. 9 ozs. of potash, equal to 13 lbs. of kainit; 2½ lbs. of phosphoric acid, equal to 18 lbs. of superphosphate of lime; and 1 lb. 5¼ ozs. of lime.

A manure to be of any value for Tomatoes must therefore contain nitrogen, potash, phosphoric acid, and lime. After carrying out dozens of experiments on Tomatoes with different artificial manures, I have come to the conclusion that a mixture of half a part or pound of nitrate of soda, half a part of dried blood, one and a quarter part of kainit, and two parts of superphosphate of lime, will, as a general rule, give the best results of any artificial fertiliser on a sandy soil or sandy loam.

The following mixture has also given good results—Half a part or pound of sulphate of ammonia, half a part of Peruvian guano, half a part of muriate or sulphate of potash, and one and half part of superphosphate of lime. The above mixtures should be applied to plants fruiting in pots at the rate of 1 oz., or a teaspoonful, in a gallon of water twice a week after the first fruit is set. For plants in borders apply 2 ozs. to the square yard once a week.—W. DYKE.

OUR HARDY PLANT BORDER.

(Continued from page 334.)

GODETIAS.

PROBABLY it will have been observed in the preceding notes that we have included few annuals amongst the plants raised for our border. This omission is chiefly due to the fact that the situation and soil are too cold and wet for the majority of those that are usually raised in autumn to flower the following season, while the spring is so late and uncertain that early raising out of doors cannot be depended upon. Still we have succeeded with some, and because the hints may be useful to those similarly situated, a few of the most reliable are here noted. First in order as regards effectiveness in masses must be placed the Godetias, of which two varieties have proved extremely useful summer flowering plants.

Several of the best of the Evening Primroses, the *Oenotheras*, are grown, and the Godetias are near relatives of these, differing, however, in two characters, which are well marked popular distinctions—namely, the absence of the yellow colour, which is general in the *Oenotheras*, and in the opening of their flowers not being so much controlled by the sunlight as to come under the heading

“evening” flowers. Still, they are influenced by very bright weather to some extent, for the flowers do not open so freely as on slightly duller days, but they expand well if cut and placed in water in a room, and they last well, too, under such conditions, much better than many annuals do when similarly treated.

Ordinary well-dug and fertile soil suits Godetias well, but they do not require a quantity of rank manure; indeed, if nothing is available but fresh stable or farmyard manure they are better without such additions altogether. In my experience this applies to many other annual plants that are cultivated for their flowers, and except where the soil is very light and deficient in humus, or it can be prepared some time in advance of the sowing or planting, I have found nothing so safe and satisfactory as a light dressing of superphosphate of lime with potash derived from burnt rubbish and clearings, or kainit. As previously noted in several letters, 1 oz. to the square yard of superphosphate or kainit, and about half the quantity of nitrate of soda or sulphate of ammonia are sufficient, but the two latter stimulants are seldom needed for the smaller-growing annuals.

Godetia seed can be sown out of doors, or in a frame or greenhouse, as it germinates readily without artificial heat, and if sturdy well hardened seedlings are ready for planting out in April and early May they develop into good flowering specimens. If sown in the open border the seeds must be scattered so that the plants have sufficient space, or early thinning should be resorted to. As with many other plants self-sown seedlings produce the strongest plants provided the soil is not allowed to become exhausted, and I have beds that have been retained in this way for several seasons. The only attention they have needed has been a light dressing of roadside scrapings with a dusting of superphosphate annually, either after cutting away the old plants or in early spring; and thinning the seedlings where too crowded. Masses 6 feet in diameter have an excellent effect, especially if the light and dark colours are contrasted, that is, in separate but neighbouring beds, as when mixed they do not look so well except in small borders.

Two varieties are far in advance of all the others for growing in the way indicated, and these are Lady Albemarle, rich bright crimson, with a beautiful satin-like gloss on the petals, and Duchess of Albany, pure white—a particularly handsome plant. Both have large flowers, produced in profusion, and the habit is compact yet vigorous, branching freely, and reaching the height of about a foot. But dwarfier selections from these are now offered by seedsmen, and for some purposes they are preferable to the others, but if a good strain of seed is obtained the ordinary types are the best for large beds. Charming varieties of less distinctly marked characters have received names, such as Satin Rose, which is one of the best known, Bridesmaid, Ladybird, Apple Blossom, and Duchess of Fife, all possess bright and beautiful flowers, or in a good mixed strain many similar variations will be found. Though not possessing the range of colour seen in some popular favourites yet the Godetias have much to recommend them to notice, and it is rather surprising that they are not more generally grown.

SWEET PEAS.

Lathyrus odoratus has received keen attention from seedsmen and others interested in their improvement, and the result within quite recent years is, to say the least, astonishing. Perhaps there is not another annual flowering plant in general cultivation at the present time which has so much to recommend it as the graceful *Lathyrus*, familiarly known as the Sweet Pea. In colours alone there is a most unusual range, for not only are there pure white and a near approach to black in the darkest of purple shades, but we have pure blue in many tints, rose, crimson, and scarlet, with intermediate shades innumerable, while a distinct shade of yellow has also been secured. Scores of varieties have received distinctive titles, and many have been honoured with certificates by the Royal Horticultural Society's Floral Committee, the members of which seem to have a very excusable weakness for these delightful plants; yet I have found that a good mixed strain from any well-known seed firm will give all the variations that can be desired. The grower then has the privilege of naming the seedlings himself if he wishes them named, but they do not appear any more beautiful or useful because they are labelled “Messrs. Somebody's Extra Special Gigantic Rainbow Sweet Peas.”

We are grateful to the seedsmen for the excellent work they have done in improving so many of our garden flowers, but we do not always appreciate the multiplication of names. This, however, is only a personal fancy, and if anyone has an inclination for a collection of plants representing the nobility and the celebrities of the present times, they can easily satisfy themselves with the Sweet Peas, for they have been honoured with names from Her Majesty downwards, including a liberal allowance of princesses and duchesses.

Apart from all other considerations, however, Sweet Peas are

amongst the most useful annuals that can be grown wherever flowers for cutting are in demand. They last well when cut, are produced over a good portion of the summer months, can be used for vases, bouquets, or bunches, and their fragrance is of that delicate and agreeable nature that does not overpower or satiate.

Sweet Peas prefer a moderately light, rich soil, but no better aid can be afforded them than superphosphate, in small dressings. If the seeds are sown in the autumn in favourable situations strong plants will be making progress at the present time; but seeds can be sown out of doors now, and in some cases with much better results, at least for the bulk of our plants we rely upon sowing in April and early May. If grown simply for cutting purposes a few rows may be sown like garden Peas and duly staked, but they are seen to much better advantage if they can be allowed to trail over old tree stems or roots, up trellises or round summer houses. The habit of the plant is naturally so graceful that it seems almost deplorable to see it confined to rigid limits or formal stakes.—A COUNTRYMAN.

ANCIENT AND MODERN CUCUMBER CULTURE.

It is a far cry to 1837, a date upon which for so many reasons our thoughts are now often directed, but in ordinary garden practice there are few things in which more change in cultural methods has been effected than in growing Cucumbers under glass. Even half a century since Cucumbers were almost exclusively grown in frames or pits on masses of fermenting manure, and in such soil areas as would make present-day growers marvel how the plants became productive.

The labour involved in the preparation of the manure, getting enough to either constitute a good-sized hotbed or to fill pits and supply effective linings, was great, and added to all this labour was that of having, especially early in the season, to keep up thick linings, so that the heat generated in the original beds might be both conserved and assisted as long as possible. It still remains in lively remembrance the difficulty of maintaining the desired warmth, and the disastrous suddenness with which it would collapse under cold, heavy rain or snowstorms, or sudden and severe falls in the temperature.

Then the big heaps of soil put into the frames or pits, usually at the first a good wheel-barrowful to a mound for each pair of plants, and as the roots showed themselves on the surface other two barrowfuls, or perhaps more of soil was added, until the plants had enough of root area for a dozen, while beneath the soil was a mass of rich manure, into which the roots running soon bred gumming, yellows, disease, and death. What wonder if the growth in stem and leafage was excessively luxuriant, rendering severe thinning absolutely essential, and making the production of fruit difficult. Still farther, the varieties then grown were, if long, rather coarse in appearance and poor setters; or if free setters then were short, and of no appreciable market value. Altogether, having regard to conditions under which grown and the great amount of attention constantly needed, Cucumber culture, whilst severely testing a grower's capacity, was far from being pleasant or profitable employment.

How different are things now. We must not forget, however, that for the change, apart from better knowledge, we owe an immense deal to the removal of the tax on glass, once so oppressive, and to the introduction of heating by hot water; still the very best, and indeed the only reliable method of heating glass houses. By this help we can now not only erect glass structures of every description easily and cheaply, but we can with the aid of a little ordinary skill set up our own heating apparatus. My thoughts were in this way directed the other day when in one of Mr. Mortimer's Cucumber houses at Farnham, Surrey, I saw the extreme simplicity of his method, with the splendid results obtained. Low span houses amply supplied with hot-water piping and furnace power; over the pipes placed on each side of the houses are erected wooden troughs, the farther ends of the bearers resting on a stout piece of quartering fixed to the side walls, the inner ends on uprights. On these bearers are laid stout wooden trellises in long lengths, and to each side is fastened a clean planed strip of wood in long lengths, and 7 inches deep. The troughs thus formed are of any length, according to the house, 18 to 20 inches wide, and 6 inches deep inside. The compost is far from being the Cucumber grower's ideal. Needing so much, and finding good turfy loam difficult to get, recourse has to be had to roadside turf and trimmings, which is carted in as obtainable and heaped to decay. This contains considerable grit as well as fibre, and to it is added some well decayed manure, though not excessively, and a moderate quantity of "Thomson."

The coarser or turfy portions are first laid in the bottom of the trough covering the trellis, and over that the soil just as it is,

rounding it up in the centre, so that the depth about 7 inches. The plants are put out about 18 inches apart; hence, as will be understood, root room is very restricted, and there can be no top-dressing with soil. When the plants get well into bearing, which they soon do, carrying great crops of splendid fruit, all the other assistance given is in the form of artificial manure dressings, or applications of liquid manure. No sooner is a big crop of seed fruits gathered than out the plants go, also the soil and the troughs. These latter are whitewashed with hot lime, then returned to the house. New soil is furnished, fresh young plants inserted, and a second crop of fruit is soon obtained. In this way eelworm and fungoid attacks are avoided by Mr. Mortimer.—A. DEAN.

CATTLEYA LAWRENCEANA.

THIS superb Cattleya is one of the most brilliant of Orchids flowering just now, plants with three or four of the fine spikes having a very bright and effective appearance. It has been known to botanists since about 1840, when it was first discovered in British Guiana by Sir Robert Schomburgk. But to Messrs. Sander and Co. the credit of its introduction to cultivation is due, a collector in the interest of this firm having sent it home in quantity about 1884. The flowers are 5 or 6 inches across, the sepals and petals rosy purplish, the lip similar in ground colour, blotched with purple crimson. The habit is like a strong *C. Mossiae*, but both bulbs and leaves have a reddish bronzy tint.

C. Lawrenceana is as easy to grow and free blooming as *C. Mossiae* or any of the labiata section, but requires more heat and almost full exposure to the sun. The pots need not be large, but must be thoroughly drained, the crocks coming about three parts of the way up, and being covered with a layer of rough sphagnum. For compost moss and peat may be used in equal proportions, plenty of rough bits of charcoal or crocks being added to it or introduced as the work of potting proceeds. The less the plants are disturbed the better, once in three years being quite often enough for repotting, a little top-dressing being allowed in the intervening seasons.

Great care is necessary in turning the plants out of their pots, as the roots are much smaller than those of some Cattleyas, and cling to these with great tenacity. It is much better to break the pots with a hammer, and introduce the pieces with roots attached in the new ones, than to risk injuring the plants by laceration of the roots. In fixing them in the new pots let the principal lead be kept as near the centre as possible; this will prevent their "growing out of the pots" before another renewal is necessary. Keep them up, and finish the line of compost so that the leading bulbs just rest on this.

Care is necessary after repotting, just enough moisture being allowed to keep the roots alive and prevent shrivelling. From the time growth starts until the sheaths are formed and the pseudo bulbs finished, the plants must be kept in a hot and moist atmosphere, such as the evergreen section of *Dendrobiums* delight in. This is, in fact, the principal point in its culture, and no other Cattleya except *C. superba*, a species found growing naturally in proximity to it, requires so much heat. Keep it free of insects and to its proper annual routine of growth, and it will, if suitably treated in other ways, produce a large quantity of its lovely blooms in due season.—H. R. R.

FLOWERS AT WATERLOW PARK.—Inhabitants of North London dwelling in proximity to the above public resort have now facilities for viewing and appreciating many seasonable flowers of more than ordinary merit. Mr. Pallett, the able superintendent, has made the most of the means at his command, the result being that Waterlow Park now presents a floral picture both attractive and interesting. At one point huge clumps of *Alyssum saxatile compactum* are conspicuous, being masses of golden yellow blossoms, and dotted here and there are *Aubrietias*, *Silenes*, *Myosotises*, and other seasonable flowers. Wallflowers form another picture of more than passing interest, as some half a dozen distinct varieties are grown. Amongst these Blood Red and Belvoir Castle strains are prominently conspicuous, and contrast pleasingly with the varying vegetation all round. Grass everywhere looks green and refreshing, and the well kept appearance of turf and gravel walks reflects credit on the superintendent and his staff.—F.

PRECEPT AND PRACTICE.

PICTURESQUE GARDENING—WATER.

(Continued from page 387.)

CONSIDERING the prominent part which water—under its various forms of lake, pool, stream, or streamlet—plays in picturesque gardening, no excuse is needed for stretching our outline in order to embrace it. Moreover, if only for the purpose of cultivating our beautiful aquatic or semi-aquatic plants it is worthy of attention. Obviously all places do not possess this feature developed in ratio to its merits, and others there are again in which its charms are conspicuous by their absence; but few there are, indeed, in which a spring or other inconspicuous water source cannot be turned to good account. Here, as with other phases of developing Nature, or attempting to create it in fac-simile, overstraining for effect may defeat the object. Planning and planting are the primary heads under which this sub-subject presents itself for consideration.

Its employment as a part and parcel of the classical outline of formal gardening necessarily insists upon harmonious blending with it, hence we see cut stone basins and fountains on the smaller scale, whilst on the larger architectural lines run parallel with the principal object, as exemplified in the treatment of the lake at Trentham Hall, Staffs, where the Italian garden is linked to the lake by a handsome balustraded parapet. In this instance, too, is to be found that happy union with Nature and Art whereby no violent contrasts are presented, and the critical eye finds satisfaction in ample breadth and rests in repose on its limits in the distance where woods descend in a natural manner to the water's edge. With this phase of our subject it will be noticed that the planning of bridges is of equal importance whether they be near to or far from the mansion, if visible from it; for if so, they are perforce included in the general design.

But it is to picturesque gardening this paper directly pertains, and it is here this free element gives, or can give, to us as gardeners the most pleasing results. The best designs under artificial treatment are obviously those in which no design is apparent, and bad examples are those which are stiff in outline and of distinct basin-like formation from confinement between banks formed by excavated soil thrown up in making or enlargement. This, however, is not of frequent occurrence, as the lake generally originates in holding back the water by a dam or weir. Islands or islets, if properly disposed and not too lavishly introduced, make an admirable break to an expanse provided that they do not exceed in height the level of the margin. An island as a hump in the water is but a sorry thing, and when further emphasised by a thick planting of vigorous growing trees it is decidedly *de trop*.

Possibly it is not until we descend to the minor key of our harmony in the way of pools and streams or streamlets that our controlling, creative, or manifesting hand is called into requisition, and probably most will agree with me that it is a charming subject and worthy of our best efforts. Our stream, which may be little more than a trickling spring anxious to escape unnoticed at its own sweet will, may be held back at intervals by a little obstructive rockwork naturally inserted in its bed, and by other auxiliary means readily suggesting themselves under varying circumstances be made into a thing of beauty, and with suitable planting, of which in due course, become a source of infinite interest in this most interesting kingdom of picturesque gardening.

Here there is no more delightful object than a rustic bridge with creepers trailing to the water, if it is necessary to have a bridge, or, what is equally to the purpose, made to appear as necessary; otherwise, the purposeless descends to the puerile, and we will have none of it. Rustic bridges of even very primitive construction, which is often the best, are such a pleasing feature in this department that an excuse may occasionally be found for having one to span a ravine or other natural break with the happiest effect. Such auxiliary means to an end involve practically no expense. Our prehistoric ancestor probably found his bridge in a fallen tree; but as we have lost his prehensile qualifications our bridge, if in its simplest form, will necessarily carry the passenger without fear and trembling. I have seen a charming example of this work erected by a handy man, and a little visible bareness in the handrail was corrected by some spare virgin cork.

Stepping stones may in some instances be advantageously employed, particularly in a bog garden, which is only second in point of interest to water gardening proper, and there are few places where even the deficiency of a natural water supply prohibits more pretentious things that do not afford of something being done in this direction. But this, the simplest form of our subject, will not assert itself aggressively. In some secluded nook or retired position where the liquid element is provided and such shelter as the depths of a wood or other means afford from chilling winds or severe frost,

certain plants are provided with a happy home that a more obtrusive position fails to give. With an old quarry revealing on its face the natural strata of rock, a little further excavation at its foot provided a catchment for surface water and an opportunity for planting a couple of M. Marliac's beautiful hybrid Nymphæas which were too precious for relegating to greater freedom.

Over the whole subject there is a natural affinity between rocks and water which can hardly be disregarded. There is something particularly pleasing at those points where a piece of natural rock peeps out from the river's brim or the margin of the lake. In those localities where Nature has denied this privilege I have seen a few introduced with the best effect, and this without any elaboration of detail. We may in this instance plant our rock, or fragment of rock, by literally burying it on the flat, showing little more than a face turned to the water, exactly like what may be often observed in the water-washed course of some stream. Obviously the employment of any kind of stone foreign to the locality would be an incongruity. A little taste, on the lines of right principle founded on observation, can do much in this direction, and what is simplest is often safest, leaving no room for invidious comparison.

One thing I should like to mention to young heads—viz., that it is often their own hands which alone can carry out their ideas. More than one long day have I spent at this work to go home at night tired out, wet through, and dirty all over, but generally satisfied. In the matter of building waterfalls, the chief object of which is the retention of water with the view of having it for effect (or for use perhaps) when most needed, I have suffered too much disappointment from tradesmen's work to trust the matter entirely to them; so much so, that in one very pretty stream we had water and waterfalls in wet weather, but during a spell of drought dry walls and empty basins. Imperfect work of this kind is practically beyond redemption, and wherever or whenever this work is worth doing it is worth doing well.

Our wall, we will call it such, although the name should never be applicable when completed, may often require sinking below the bed of the stream, and carried for some few feet into the bank on either side. I have found it a perfectly satisfactory method to arrange the stones, when selected, in a double wall with an intervening space of, say, 18 inches, which, filled up as the work proceeds with liquid concrete, binds all into an impervious structure. Facilities for letting off the water, should it be advisable to provide for that contingency, can be had by leaving a trap at the base, the setting or construction of which will present little difficulty to an ingenious mind.—AN OLD BOY.

(To be continued.)

IN SEARCH OF SUNSHINE.

THE CITY OF THE FLOWERY PLAIN.

(Continued from page 409.)

THE bulb farms are often kitchen gardens. Most of the growers take a crop of Potatoes off the land before they put bulbs upon it. One of their favourite varieties is about the finest flavoured Potato I ever tasted, and if it maintained its splendid quality on our stronger British soils it would soon be run after. That, however, is extremely doubtful, and it would very likely be worthless on clay. Its name is Wolkhammer. It comes in about January and lasts good till June. The Dutchmen claim to have an early variety of equal merit in the Stegerhoek. Grown in sand enriched with cow manure both of these varieties crop well and cook beautifully. They form a very important dish on the tables of the poorer people; indeed, meals are made of them. A dish of about half a bushel graces the middle of the table, and near it is a large bowl of sauce. Round the table sit the family (usually twelve to fourteen), and in turns each member transfixes a Potato, dips it in the sauce, and crams it whole into his mouth. One gulp disposes of it. It is not uncommon, when wandering through a village at mealtime, to see a fat and grinning child come running to the window with a large Potato spitted on a fork. He holds it out to you, and while you gaze enviously he whips it into his mouth as quickly as a toad would a woodlouse, and swallows it without a blink.

It seems odd to us, but is after all not surprising, that an experiment with Magnum Bonum turned out a failure. One of the growers imported some and grew a good crop; but it was not known on the market, and the growers would have nothing to do with it. Potatoes are not planted in a lined trench as with us, but are simply dropped into a hole made with a large dibber. The plan answers as it would not do on the Wealden clays. Husbandry in general is, in fact, altogether lighter and simpler. The labourers

use a large shovel nearly heart-shaped in digging, and work very rapidly. Forks are useless; the soil would fall between the tines like water through a sieve. Trenching is trenching in Bulbland. It is not uncommon for the soil to be turned up 5 feet deep; in fact, it is the rule to turn the top soil right down every three years or so, as it gets bulb-sick. The subsoil brought up is not sour, nor does it look unkind. Manured and cropped with Potatoes in spring, it is in good condition for bulbs the same autumn. No doubt the porous nature of the soil, combined with the vigorous stirring it receives, secures aëration at a far greater depth than would be possible in strong land.

Asparagus grows to perfection, as might be expected. Dirk the Dutchman does not share our partiality for green nobbs. He likes his Asparagus white, and plenty of it. As soon as the heads show a spade depth of the soil is turned on to the top of them, consequently they grow to a great size and blanch. "Ah!" someone may remark, "what about the toughness?" My dear sir, it melts like marrow. When cut the Asparagus is usually put into water and eaten the same day. Perhaps if it were kept a day or two and then sent over to England, a week elapsing from cutting time to use, it would be as tough as a good deal of the French is. So far as can be learned, no particular care is taken in the cultivation of the crop. It grows, as Asparagus will grow, on porous sandy soil not many miles from the sea. I am inclined to think that a profitable trade could be done in it, the natural conditions being so favourable; but the growers have something better to occupy their attention.

Another vegetable grown under different conditions from those which exist in this country is variegated Kale. The Dutchmen have some very good strains of it, quite as good as, if not better than, our own; and having got them they are not afraid to use them. In the grounds at the front of many large villas are seen circular beds filled with these Kales. The plants are about 2 feet high, of a good pyramidal habit, and beautifully coloured. They are genuinely handsome, and although they do not secure very much attention in bulb time they do in the dull season, imparting an agreeable warmth of colour to bare surroundings.

The city of the flowery plain is gay and lively in the glowing springtime. Its handsome streets, fine houses, historic church, galleries, and interesting crowds make it something more than a centre for the bulb villages; but features such as those I must pass. Scarcely a mile away is the nursery of Messrs. Ant. Roozen and Sons, one of the most attractive to the amateur. A steady walk for about ten minutes straight from Haarlem Market place took me to a villa surrounded by bulb beds, and rising from the latter was a bold name board. It was enough, although both board and villa were new. Great extensions have been made since my last visit. More houses have been built and more land taken. There is an air of substance about the whole establishment which inspires respect. The drying stores, packing houses, and offices are handsome, spacious, and of the best construction. There is a temptation to overlook these evidences of strength in the brighter, but more ephemeral, pictures of the beds, but they are worth mentioning for all that.

History repeated itself in one respect—the stalwart sire was absent, but two stalwart sons represented him. I was interested at the outset in a splendid house of Amaryllis, chiefly because they represented our best types. Well-rounded flowers of great substance and rich firm colours were conspicuous among a beautiful batch of novelties. They are a new departure I understood, and represent a wonderfully good start. It may be taken for granted that any class of bulbous plants which finds favour in England will very soon receive the attention of these wideawake Dutchmen. In anything that affects their own line of business they are as watchful as cats. There is something instructive in the plasticity displayed all over the Continent in whatever concerns John Bull's spending department. Our language is thoroughly mastered, our country is tramped from end to end, our methods of trade are studied. A take-it-or-leave-it air is never assumed. There is no pretence that the universe is eagerly bent on getting some particular class of goods. On the contrary, the prevailing notion is that what people want shall be supplied to them, and if it does not exist it must be brought into being, and put on the market at the earliest possible moment.

Economic homilies being pardonable only as a digression, I return to my muttons. Messrs. Ant. Roozen & Sons give a good deal of attention to John's partiality for something new. It is a weakness of his to keep trying fresh things, and they are thoroughly familiar with it. I had a ramble round their novelty department,

and did not go unrewarded, although many of the plants I saw were not in flower. For instance, the beautiful double white Colchicum (*Colchicum autumnale albo-pleno*) was not flowering, but I was not surprised to hear that it is in considerable demand. The same with the white Pasque Flower (*Anemone pulsatilla alba*), a most pleasing and attractive novelty. *Allium giganteum* is being asked for, and so is *Deutzia Lemoinei*. I saw a charming novelty of the Dog's-tooth Violet race in the form of *Erythronium grandiflorum* var. *citrina*, pure yellow and very beautiful. Amongst the Hyacinthus or Muscari there was *comosus albus*, a white sort.

FIG. 87.—IRIS LORTETI.

These are not a largely grown class, but to see them in massed beds in Holland is to fall into prompt and permanent admiration.

There are two genera which are grown on a truly enormous scale at Overveen; one is Iris, the other Pæony. To say that these are cultivated by the acre is a very mild assertion, innocent of any shadow of exaggeration. It would be almost worth a journey to see them in flower, the Pæonies in particular, but that, of course, would have to be later than mid-April. You may get the late Hyacinths and the early Tulips at Easter, but you will not get Irises and Pæonies in quantity. Amongst the newer Irises in considerable demand are Bakeriana, Gatesi, Lorteti (fig. 87), Milesi, Rosenbachiana, and sindjarensis. Pæonia Whitmanniana is greatly asked for, and in addition to this beautiful creamy Caucasian species there is a very large assortment of the best varieties of other sections. Pæonies grow luxuriantly and flower magnificently in the Haarlem sand, and perhaps the principal reason is that they have a deep and uninterrupted root run. When the lustrous Pæony can stretch his toes down several feet, then is he gay, joyous, and prolific.

Crib him, cabin him, confine him, give him a tough sole 6 inches below the surface, throw his roots up to the heat instead of down to the moisture, and he exacts the cruel revenge of barrenness.

Amongst the comparative novelties there are *Lachenalia Regeliana*, with light yellow horizontal flowers; *Lilium Grayi*, *Owstrowskya magnifica*, *Physalis Alkekengi Francheti*, *Sternbergia macrantha*, *Tritoma hybrida* R. C. Affourtit, and several Tulips. *Bouton d'Or* is a very pretty bright yellow species; *Kaufmanniana* is a fine cream, and *saxatilis* a charming rose and yellow. The early Dutch varieties are indescribable, both as to numbers and character. I can only say that *Golden King*, a splendid double yellow, selected from *Tournesol*; *Golden Queen*, a fine single yellow; *Grace Darling*, the true *Scarlet Pottebakker*, a magnificent variety; *Jenny*, a beautiful rosy red; *Pink Beauty*, and *Queen of the Netherlands* struck me as being amongst the best of the Tulip novelties.

They have taken me back into the fields again, those wonderful fields of light and colour, of all things gay, of Nature in one of her many aspects of bewildering beauty, of perfume, of sunshine, and of birds' songs. There I linger, and there I return for many a morning, and afternoon, and evening of pure enjoyment. When at length I leave the city of the flowery plain and its surroundings, it is from a little railway station bearing a name that, translated, means "the song of the birds," and which is situated in the midst of a great lake of vernal beauty. And of the ceaseless twittering there, the wayside fragrance, the exquisite flowers, sweet remembrance will come, perchance to freshen the aridity of the years that are to be.—W. PEA.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE, MAY 11TH.—Present: Dr. M. T. Masters (in the chair); Mr. Douglas, Mr. McLachlan, Rev. W. Wilks, Dr. Müller, Dr. Bonavia, Mr. A. Sutton, and Rev. G. Henslow, Hon. Sec.

Weevils on Fruit Trees.—Mr. Rbt. Smith of Shrewsbury forwarded some living specimens received by him from Mr. J. Jones, Chelmick Pools, Church Stretton. They were described as attacking Plum and Apple grafts, Roses and Raspberry buds. They proved to be *Otiorynchus pisipes*. The trees and bushes might be sprayed, though a better plan is to shake the boughs over a large sheet of paper, in which they can be caught and then destroyed.

Birch Branch with Phytomyza.—Dr. Masters showed specimens illustrating the early stage of the attack on boughs by this insect. It is not often the commencement of the so-called "Witch Brooms" can be detected as in this instance.

Abies bracteata.—He also exhibited sprays of this handsome tree, remarkable for the silvery under surface of the leaves, which are about 3 inches in length. It bears large male catkins, and elongated pointed buds. It is a native of S. California. It is remarkable that it fails to flower on the Atlantic side of N. America.

A. Menziesia.—He also showed a bough of this splendid timber tree from Vancouver.

Petalless Apples.—Flowering shoots of the Ecklinville (Seedling) Apple were received, remarkable for having no petals. They were sent from the Glewstone Gardens, Ross. There were 600 bushes of twelve years' growth, all being similarly affected. No particular cause could be suggested.

Double Narcissus.—Dr. Masters showed a single and double flower of a *N. incomparabilis*, of a somewhat novel character. The perianth consisted of twelve pieces regularly arranged in "threes." The short cup-shaped corona as well as the stamens were totally absent; but the styles above the tube were free and petaloid, suggesting the normal condition in an Iris.

Sclerotia (?).—Mr. M. Taylor, of The Gardens, Penbidw Hall, Nannerch, sent some remarkable specimens of a fungus consisting of large branching lumps, which appeared in a Mushroom bed. They were forwarded to Kew for investigation.

Improved Method of Grafting.—Mr. Robt. Smith, of Bradwell Villas, Bishop Street, Shrewsbury, sent a number of specimens of grafts, illustrating a new method. This being, that in preparing the scion, while one "tongue" is inserted as usual, the opposite half of the scion is carried over the flat top or "crown," and inserted on the opposite side, or two grafts may be thus inserted on opposite sides of the stem, the result being, as shown in the specimens sent, that the summit is completely covered in with new growth. This was seen in small specimens of whip-grafting, but none were sent to show how far large crowns would become covered over. Another advantage arose from the new method of preventing loss of grafts by wind breakage, for it thus gave a better and stronger union. It was thought by Mr. Douglas that it was a decided improvement upon the old method, as long as the scion and stock were of the same size; but further information was desirable as to the success when the surface of the stock much exceeded that of the scion.

Double White Auricula.—Mr. R. Dean sent a plant, which was the result of fifteen years' selection from a single white variety; the petals were not of a pure white, but slightly yellowish-green tint.

WINTER IN MAY.

AFTER passing through a mild winter, when the lowest point reached on the thermometer was 14°, or 18° of frost, on the night of the 10th inst. we had 8° frost registered by the thermometer 12 inches from the ground. On the 11th a heavy shower of snow fell at 5 P.M., but the morning of the 12th will long be remembered, for the thermometer registered 12° of frost. Of course Potatoes are blackened; Gooseberries nearly ready for tarts; about seven-eighths of the crop gone, turned to an ashen-grey colour, and just on the point of falling; Currants in a similar plight. Fortunately the Strawberries were not sufficiently forward to be damaged. It is too early to estimate the amount of damage done to orchard fruit.—JOHN CAMPBELL, *Mickleover Manor Gardens, Derbyshire*.

THE frost on the night and morning of May 12th-13th has done much damage in Worcestershire to Strawberry blossom, Peas, Potatoes, Asparagus, and Plums. Of the latter the standard "Egg Plum" or "Pershire," appears to have suffered the least injury. The injury appears to have followed the greatest atmospheric moisture, because in the same fields, which are generally level, some patches of Peas are injured and others are unhurt; the difference in elevation being only a few inches.—J. UDALE, *Droitwich*.

AFTER the terrible frost of last week, "No fruiting this year" was the cry of village folks. I thought, being a beautiful morning, I would take a stroll round a few Strawberry fields, and see the results. Going through some of Mr. Hooper's fields I could not help noticing black eyes by the dozen on each root. Plant after plant was the same; every bloom was destroyed, and hundreds that were not open were in the same sad state. What the effect of this frost on Strawberries will end in is hard to describe. Plums, Damsons, Pears, Apples, and all other fruits are the same. Peas with young pods have perished; Potatoes all cut to the ground. It was a terrible sight.

Tomatoes indoors are dreadful; flagging is the enemy. Day after day we are constantly pulling up and planting. Such strong healthy plants the day before suddenly fail; it seems to me a mystery why they should go so quickly. Blooms do not set well, and what fruit there is does not swell. One large market nurseryman has had 500 to 600 plants go off in that manner in five houses of 100 feet long. I have pulled some up and cut the plants off about 3 inches from root and found the stem under the rind quite hard, so that no sap could pass and support the foliage. What is the cause, Messrs. Abbey and Dyke, and what can be done in the dilemma?—H. PEARL, *Swanley, Kent*.

VERY poor hopes of a good fruit crop for the present year are already being expressed by gardening friends, because of the long spell of bitterly cold north-easterly winds that have prevailed, and the numerous sharp frosts experienced. Most distinctly Pears, Plums, and Cherries first, then Apples, have had to endure during their flowering worse weather than was experienced when Peaches and Apricots on walls were in bloom. An old rural saying, that where the wind is on March 21st, there will it be till midsummer, seems likely to be realised this year, for it does stick in northerly and easterly quarters very much. Naturally we shall look this season for the fruit returns that will be made later on with special interest. How useful would it be could we learn how 'ar trees sheltered by forest or other tall trees had been less injured than were trees fully exposed to the winds. Pears, Cherries, and Apples have produced a marvellous display of bloom, but how often in the experience of old gardeners has it been found that such floral masses have been the precursors of a good fruit crop. The present season, whether due to that or to low temperature and wind, seems likely to be no exception. It is, indeed, intensely disappointing. Here is one eminent gardener's report to hand:—"Apple bloom is looking exceedingly crippled; Pears are dropping badly where they had appeared to be well set; Plums will be rather thin; Cherries good if they do not fall; Peaches and Nectarines a full set, but leaves much blistered with cold; Apricots thin." From other directions comes information that Currants and Gooseberries are falling, and frosts have done harm to the early Strawberry bloom.—A. D.

THIS district, in common with many others, was visited by an unusually sharp frost on the morning of the 13th inst., causing irreparable damage to the early and second early Potato crops, and also Strawberries, which were coming into bloom. In the open quarters every plant was cut down, as also were those on south borders; but, strange to say, on an east aspect much less damage was done. In the open fields the density of the hoar frost in the early morning was extremely wintry, and on the broad foliage of Cabbage and Broccoli in the garden it had much the appearance of snow particles. Broccoli had the appearance of being spoilt, but being a dull sunless morning, so unusual after such frosts, the damage done was very slight. French Beans growing at the foot of a west wall did not suffer much loss, and fortunately there were no Runner Beans sufficiently forward to be affected. Asparagus, too, escaped what I fully expected to be the loss of a morning's cutting. The early Strawberries suffered badly, the majority of the expanded flowers now showing black centres. Late ones are unhurt. Rhododendrons in flower were all spoilt, and Ampelopsis growing over arches lost many of their leaves. The spring has been very cold and backward, or the same amount of frost might have caused much greater injury. Our thermometer indicated 6° of frost, but outside

the garden it must have been several degrees colder, judging from appearance in the open fields.—W. S., *Rood Ashton, Wiltshire*.

[We have had many allusions to the damage done by the frosts of last week. We hear the first blooms of Strawberries, which invariably give the finest fruits, in the extensive collection at Chiswick are blacked, as they are in numbers of other gardens in the South. In one instance the later buds are said to be killed. In passing through Mr. A. H. Smee's interesting garden in Surrey the other day, we observed that his gardener, Mr. Cummins, had been on the alert and saved a square of Potatoes by covering them with hay, the plants in one row left uncovered being cut to the ground. The full extent of the injury done to fruit crops generally is not yet fully ascertained.]

PLANT CONSTITUENTS: SODA.

(Concluded from page 368.)

WHEN washing soda is used as manure it is crushed fine and distributed broadcast at the rate of half to 1 oz. per square yard, 1 to 2 lbs. per rod, 1½ to 3 cwt. per acre, the price wholesale being about 5½d. per stone (14 lbs.), 3s. 6d. per cwt., bag included. For "greens" it is given at the time of setting, usually the lesser quantity, and if occasion require repeating the dressing before winter, but keeping the soda from the hearts of the plants. It is good for everything liable to grow too much to top, especially crops prone to suffer from succulency of growth during frost in autumn, winter, and spring, and answers for either vegetables or fruits. It is especially valuable for winter Spinach, Strawberries running too much to leaf, and all plants that need solidification and fortifying with silica. It is better than salt for most crops, as it supplies the soda without the chlorine, which is apt to retard the growth too much in growing for market.

Sodium sulphate, or sulphate of soda, Na_2SO_4 , 142, also called Glauber salts and salt-cake, is a compound of sodium and sulphuric acid. In the crystallised state it contains about 56 per cent. of water, and when exposed to the air it yields by parting with its water of crystallisation the anhydrous (that is, without water) salt, a good commercial article containing from 94 to 98 per cent. of sodium sulphate. It is sometimes obtained as a bye-product in the manufacture of nitric acid from nitrate of soda, when the sulphate contains small quantities of nitrate of soda, and thus has better fertilising value. The manurial property depends on the sulphur; this, in the form of sulphuric acid being supplied to the land and plant, hence sulphate of soda has been found to be a good manure for cereal and leguminous crops, especially on light soils.

It should be applied in a fine powder at the rate of ½ oz. per square yard, 1½ lb. per rod, 2½ cwt. per acre, which is a suitable application for crops—cereals, Clover, grass (including lawns), Beans, Peas, and Potatoes—generally. It is a "growing" manure by virtue of the sulphur, therefore should be applied in the spring or when growth is desired, which can only be when the heat and moisture favour. The soda certainly profits both fruits as well as grasses, and legumes on light gravelly soils; but the sulphur can do little good on moist land, and the soda left may do harm. Sodium sulphate mixes easily with nitrate of soda, phosphates, and other manures, there being generally plenty of it in "special" manures for Bean, Clover corn, and Potato crops.

Sodium chloride or common salt, NaCl , 58.5, has been used as a manure from very ancient times, but its action upon plant life is little understood; yet that on the soil is known to be chemical and mechanical, and the resulting changes beneficial to many garden and most farm crops. It is used to some extent on grain crops, especially on Wheat, to prevent excessive growth of straw, brightening and toughening it, consequently better enabling the plant to resist the attacks of rust and other parasitic fungi. It also acts well against weeds, root insects, and molluscs, retaining moisture in light soils, while its action upon soils rich in nitrogen restrains the growth of the plant, which may be due to the chlorine killing, this hindering the development of the nitrifying micro-organisms, whilst the soda, or rather the salt, bodily acts on the silica, and so fortifies the plant with this substance. Salt acts beneficially in many soils by making potash, lime, and magnesia available as food for plants. It decomposes the double hydrous silicates of calcium, potassium, and magnesium, displacing first lime, then magnesia and potash and some phosphoric acid. Salt also hastens the decomposition of organic matter, "fixing" the ammonia by converting it into ammonium chloride.

Salt also possesses the property of flocculating fine earth, thus it exerts an important mechanical influence on compact clayey soils, and is otherwise useful in the soil and plant. When used to stiffen the straw of Wheat or any other plant 1 oz. per square yard, 2 lbs. per rod, 3 cwt. per acre may be applied in the spring, always by the time or a little before growth for the season commences in the plant. For Brassicas and "roots," including Jerusalem Artichokes, Potatoes, and Yams, also Tomatoes, the salt, always crushed fine, should be supplied at the time of sowing, setting, or planting out. Double the amount of salt may be employed on land for the Cabbage tribe, or in the case of crops that have to stand the winter the quantity specified may be given at the time of setting out and a similar amount in late September or early in October, but this dressing must be kept from the hearts or useful leaves of the plants, distributing it between the rows. For autumn-sown

Onions and winter Spinach the salt should be supplied at sowing time, while for spring Cabbage and Lettuce it may be applied at the time of transplanting. The object in all these cases is to render the plants sturdy and hardy, also to destroy their enemies—the slugs and other predatory pests.

For leguminous crops salt may be mixed with gypsum (ground) in equal proportions, applying 2 ozs. per square yard, *4 lb. per rod, *6 cwt. per acre. Good results follow a dressing given at the time of sowing, or in the case of autumn-sown Beans or Peas the dressing should be given in the spring, when the plant commences growth for the season. It induces sturdy growth, prevents an excess of haulm or straw, and concentrates the energies and food on the pods, securing an abundance of large and well-filled, such as only sturdy and healthy plants can produce. The mixture acts well on bush and other fruits that grow too much wood for the plentiful production of fruit, being as suitable for stone fruits as other kinds, causing lank and sappy growths to become sturdy, short-jointed, and fruitful. The mixture should be applied in the spring, when the plants are starting into growth or swelling the buds, and does not interfere with the beneficial action of nitrogenous or ammoniacal substances present or supplied to the soil, but conserves them for the use of the plant, whilst securing their acting in the most desirable way for profitable returns.

As an ingredient of general manures salt acts as an antiseptic, retarding the decomposition of ammonium urate, so that more of the urate remains available as such for the feeding crop than would be the case if nitrogenous or ammoniacal manures were used alone. It was formerly mixed in equal proportions with Peruvian guano before applying it to the land, and 1 oz. per square yard, 2 lbs. per rod, 3 cwt. per acre gave much better results, as regards a sturdier, healthier, and more productive plant, than was obtained by the use of guano alone. The guanos of the present time generally contain sufficient sodium for practical purposes, so that there is less need to mix salt with them now than was the case formerly. Nevertheless, the nitrogenous guanos give better results when a third part of common salt is added—that is, two parts nitrogenous guano, and one part salt. Salt may also be used along with nitrogenous or ammoniacal manures, the object being to counteract the tendency of these to produce exuberance of growth, and thus checking over-luxuriance secure a maximum of useful produce; for what profit is there in rank Potato tops without corresponding sound, best-quality tubers, or in luxuriant "grass" without equivalent grain, or in an exuberance of foliage without an abundance of large, clean fruit?

The need of sodium by certain plants, such as Asparagus, Seakale, and other seaside plants when grown inland is a vexed question. The chemist scores when he tells us that sodium is not essential for the production of the finest Asparagus and Seakale. † "Herapath made two analyses of Asparagus, one of the wild and the other of the cultivated plant, both gathered in flower. The former was rich in sodium, the latter almost destitute of this substance, but contained correspondingly more potassium.

ASH INGREDIENTS OF ASPARAGUS.

		Wild.	Cultivated.
Potassium oxide	18.8	* 50.5
Sodium oxide	16.2	trace
Calcium oxide	28.1	21.3
Magnesium oxide	1.5	—
Chlorine	16.5	8.3
Sulphur trioxide	9.2	4.5
Phosphorus pentoxide	12.8	12.4
Silica	1.0	3.7

"These results go to show—it being assumed that only a very minute amount of sodium if any, is absolutely necessary to plant life—that the sodium which appears to replace potassium is accidental, and that the replaced potassium is accidental also, or in excess above what is really needed by the plant, and leaves us to infer that the quantity of these bodies absorbed depends to some extent on the composition of the soil, and is to the same degree independent of the wants of vegetation."

The Beet, Cabbage and Carrot, as well as Asparagus and Seakale, are seaside plants, but they all grow well inland under cultivation and in comparative absence of sodium compounds. Which are the healthiest or freest from disease? The cultivated or the wild? This is an aspect of the question apt to be overlooked by chemists, who make out that sodium is not indispensable or that a small amount suffices for the requirements of vegetation, and that most soils contain sufficient. What about the amount of soda supplied in the commercial fertilisers, kainit, and farmyard manure (commonly 1.9)? Is there enough in these substances to meet the requirements of cultivated plants for sodium? If so, are the plants as sturdy, hardy and disease-resisting as those growing on land to which a judicious dressing of common salt is occasionally applied?

Expedient dressings, such as are often given Asparagus beds, ostensibly to benefit the "grass," but really for destroying weeds, express

* The amounts are rather more than the rate per square yard, but round figures are given for convenience.

† Johnson's "How Crops Grow," page 190

nothing but the power of some plants to resist the injurious effects of common salt, the plants certainly not being benefited. Yet the moderate use of sodium chloride is not without its corresponding advantages in hardiness of plants and comparative freedom from attacks of predatory pests. It is also useful for mixing with compost heaps, and acts well against couch grass in the land.—G. ABBEY.

SUMMER BEDDING.

I DARE SAY I shall be called over the coals about plants I intend to introduce in my bedding arrangements, and others I have purposely left out, as many will not perhaps consider them as bedding plants. However, I do not intend to confine myself to flower beds, for I consider a great many of the prettiest effects are otherwise obtained.

I will commence with flower beds, which we will suppose are in front of the drawing-room and dining-room windows, and are of good size. The design of the beds should be to suit the form of bedding you are going to carry out. I myself prefer large beds, something after the style of those in Hyde Park, not a fantastical design of small beds, which look pretty when no plants are in them and the reverse when filled. I also strongly condemn the carpet bedding system for a gentleman's residence. It is very well for the parks, but one gets tired of looking on the same thing day after day. I will now give a few of my own arrangements and the size of our flower beds, which of course might be smaller or larger to suit taste or position, but it must be borne in mind that large beds are best for large plants.

We have a centre bed 26 feet long by 12 feet wide, with rounded ends. The middle row is formed of mixed Ivy-leaved Pelargoniums, trained to three stakes 2 feet out of the ground, taking nine plants $2\frac{1}{2}$ feet apart, the end plant being 3 feet from the grass edging. Between each pair of these is a plant of *Lilium auratum*. On each side of this centre row, and 2 feet from it, plant mixed standard Fuchsias, eight plants on a side, and trained to 3 feet high, with a small head, and secured safe to a neat green stake, which runs up into the head. Between them we plant *Lobelia cardinalis*. The Fuchsias should come opposite the *Lilium auratum*s and the *Lobelias* opposite the Pelargoniums. Next take a row of Ivy-leaved kind, the same as the centre row, all round the bed and 2 feet from the edging of grass and $2\frac{1}{2}$ feet apart, and between these plant *Lilium lancifolium roseum*. Fill the whole up with mixed *Verbena*s, dwarf *Petunia*s, and *Viola Ardwell Gem*, a splendid yellow free-flowering variety, and about 6 inches from the row of "Geraniums" place a row of Sutton's Crimson Gem *Begonia* all round the bed, then a row of *Begonia Princess Beatrice*, finishing with *Ajuga reptans purpurea*. Now if you have only a small lawn this one bed to my fancy would give more pleasure during the summer, if well looked after, than six or seven of smaller size. I saw a striking instance of this last season in a large place I went to look over. A beautifully kept lawn, with an endless number of flower beds just in front of the windows, and nearly the whole bedded with Geraniums (I might say thousands of plants). I was told these had been a blaze of bloom, but, alas! the dreaded rain had come, and on the whole of these plants not a single good truss of bloom was to be seen, but just a mass of green foliage. I could imagine the contrast with this and the bed I have described.

In arranging a round bed 12 feet across place a good large *Canna* in the centre (*Ehmanni iridiflora*), round this place five dark-leaved *Cannas* (*Frangois Lapent*), 2 feet from the centre one. About 2 feet from last plant five standard Fuchsias, just opposite the *Cannas*, and between the Fuchsias plant green-leaved *Cannas* (such as *Arthur Crozy*), growing about $2\frac{1}{2}$ feet high. Fill this in with a few *Browallia elata*, *Phlox Drummondii*, mixed *Mimulus*, and a few *Gladiolus* and *Hyacinthus candicans*, edged first with *Begonia Crimson Gem*, and next *Cineraria maritima*, finishing off with *Ajuga reptans purpurea*. On a diamond-shaped bed, about 9 feet across, place a good plant of dark-leaved *Castor Oil* in centre (*Ricinus Gibsoni*), and plant at each angle a variegated *Maize*, with a good plant of *Salvia Sutton's Scarlet Queen* between them. The *Maize* and *Salvia* should be 2 feet from the grass edging. Fill in with yellow and white *Marguerites*, and dot in four good plants of *Salvia patens*, one behind each scarlet *Salvia*, and four good clumps of *Lilium tigrinum*, one behind each *Maize*. Edge first with dark-flowered *Heliotrope* (*President Garfield*), and finish with *Euonymus radicans variegata*. A good effect on an oval bed may be formed by dotting in seven trained Ivy-leaved Pelargoniums, 2 feet high, six *Swainsonia Osborni*, with six *Lilium lancifolium roseum* dotted down the centre row, filling in with *Marguerite Carnations* and *Lobelia speciosa*. Edge first with *Marigold Legion of Honour*, and finish with *Dactylis elegantissima variegata*. This grass to keep it in nice order should have the outer foliage pulled off every time the bed is edged, or it is apt to become shabby before the summer is over.

To make a round bed, $8\frac{1}{2}$ feet across, look attractive, place in the centre a *Canna* (such as *Florence Vaughan*), and three others round it, about $2\frac{1}{2}$ feet from the centre one (such *Cannas* as *President Carnot*, dark leaf and large red flowers), dot in a few well prepared *Celosia pyramidalis*, and then fill up to within 18 inches of the grass edgings with double mixed *Zinnias*; 15 inches from the grass edging take a row of *Tropaeolum Minnie Warren* and *Lobelia speciosa*, planted alternately all round the bed, finishing with *Euonymus radicans variegata*. Charming beds may be formed with tuberous-rooted *Begonias*, with a few *Liliums lancifolium roseum*, *rubrum*, *Kraetzeri*, and longiflorum *Harrisi* dotted about amongst them, and edged with *Begonias Princess Beatrice*,

Afterglow, or *Ajuga reptans purpurea*. I prefer hardy edgings to my beds, as they are there ready for the spring, and will stand two seasons very well with a little fine soil worked in and about them with the hand. The dark-leaved *Ajuga reptans* is a very useful plant; where it does well it saves me growing *Iresine*, and also comes in for a spring bedding plant. If wanted for its foliage, the blooms should be kept pinched off, but it is really a very pretty spring flowering, as well as foliage plant; sometimes the leaves decay a little in the winter, but they soon shoot out again in the early spring, and look as well as ever.

Before leaving this portion of the subject, perhaps I had better explain how I grow these plants ready for the beds. The Ivy-leaved Pelargoniums are rooted in August in the usual way, and established in 60-size pots. When these pots are filled with roots, some time after Christmas, or when the first vinery is started, they are transferred to 32-sized pots, and three stakes of the height desired placed in each pot, a wire ring being fastened to the top of the stakes the same size as the rim of the pot, or nearly so. The plant is kept neatly tied round these stakes till bedding time, and about a month after that I take no more trouble with training. The Fuchsias are rooted about the middle of the summer, and potted singly. They are kept to one straight stem, and when cold weather sets in are treated to a moderately warm house or pit, and shifted into 48-sized pots, having a neat stake placed to them the desired height (3 feet), and when they get to the top of the stake the top of the plant is pinched out about 3 inches below the top of the stake. The stem is disbudded to within three pairs of leaves from the top of the plant, and then allowed to make a small head out of these three top buds. As soon as these buds have shot a few inches the points are pinched out, and so on till about the middle of May. We then have a nice little head, which shows the bloom to advantage. About the end of March the plants have their last shift into 24-size pots, and by the first week in June are ready for planting in the beds. When planted they should be secured to a neat green stake, which runs up into the head, and the shoots all secured to the stake with green or brown fine twine. It will then take a very rough wind indeed to damage them, in fact they will stand much better than Dahlias.

These Fuchsias will do a second summer, but after that the heads get too large, and are better used for other purposes. When I want to keep them a second summer I shake all the old soil from the roots, then prune the head and roots back, pack them as thickly as I can into an old wine case, and cover the roots with garden soil and road grit, then store them away in a cold pit, outhouse, or stokehole. With about three waterings they keep all right till the end of February; then they must be potted in the usual way. I might say the place they are wintered in should be quite cool, but free from frost. Zonal Pelargoniums you will see I have left out of my bedding arrangements, for the reason I have already mentioned. They have more than once disappointed me, for just at the time I have wanted my beds to look the brightest a rain has come, and then the blooms are spoilt for several days. I should, however, recommend a few in the mixed borders, and also for vases.—(Read by Mr. W. TOWNSEND at a meeting of the Reading Gardeners' Association.)

(To be continued.)

A REVERIE.—There is always a willing public to take hold of a novelty and test it on its merits, but perhaps there is no section of these purchasers more ready to experiment than the men who grow fruit for profit, and especially small fruits. The records of novelties of Strawberries, for example, during the last few years show some very remarkable, not to say surprising, facts in this respect; hosts of varieties have been offered, hosts of growers have tried them, and the places thereof know them no more. Yet, for all that, it is not to be said that progress is not made; quite the contrary, progress goes on apace, but of the thousands of subjects offered, new and distinct though they may be, yet do they fail to prove superior in some one essential characteristic, while not falling behind in any other. Nature is not lavish in the production of marvellous departures from the normal type—freaks are unusual to her, and it is only a freak, so to speak, that can show any wide divergence from well-established lines. Nature and man are striving to two totally different ends; Nature has in view the perpetuation of the species by progeny of the individual, and her best efforts are directed towards the one end of perfecting seed. Man, on the other hand, in his demands, more frequently than not, strives to "develop" some special part of an organ to a monstrous extent, and this will be done at the expense of some other part of the plant, say in constitution or size. That plants so grown through a long series of generations do lack constitutional vitality would seem to have an abundant proof in the proneness of certain high-bred types to succumb to disease. In the event of the forcing and directing hand of man being withdrawn, Nature again steps in, and in a surprisingly short period of generations she will have brought the object of man's neglect into harmony once more with the multitude around; energy will be now directed to the perfecting of the seed, and all the luscious parts so valued by man, reduced to the extent that the necessities for their distribution will allow. In the meantime, vigour and health are regained. When man sets out to run in the face of natural law he has a hard time, and so it is that the raiser of novelties is so often doomed to failure, for Nature has the first pull, is ever present, ever ready to grab hold of the least advantage given. Nature is persistent, man is erratic.—("American Gardening.")

"JOURNAL OF HORTICULTURE" EDITORIAL DEPARTMENT.—

From the present date, and until further notice, it is particularly requested that all letters and parcels intended for the Editor, also all communications for insertion in the *Journal of Horticulture*, be addressed to 8, *Rose Hill Road, Wandsworth, London, S.W.* N.B.—Business letters and advertisements must be addressed to the City Office.

— WEATHER IN LONDON.—The latter part of the week ending on the 15th inst. was characterised by intensely cold winds that did much to retard vegetation of all kinds. Sunday brought a change to warmer weather, with a short shower. Monday and Tuesday were brilliantly fine, and the sun was very powerful. Wednesday was cooler, but fine.

— WEATHER IN THE NORTH.—Up till Thursday, 13th inst., when 6° frost were recorded, the weather continued cold and ungenial. A change then took place. Friday was dull but milder, and Saturday pleasant. Although the wind has been in the east bright sunshine has since prevailed, and vegetation is advancing rapidly.—B. D., *S. Perthshire*.

— THE TEMPLE SHOW.—For the tenth time the Royal Horticultural Society will hold its great annual flower show in the Inner Temple Gardens on May 26th, 27th, and 28th. There is sure to be a marvellous display, judging from the very large number of entries which have been received, and there is reason to believe that some of the exhibitors will show something original this year in the way of displaying their plants. The Judges will meet in the Secretary's tent at 10.30 A.M.; the Fruit, Floral, and Orchid Committees will assemble at 11 A.M., and the show will open to the public at 12.30 P.M. An interesting feature of the catalogue will be an article on the "Royal Horticultural Society" from the pen of the President, Sir Trevor Lawrence, Bart. P.S.—Owing to the great pressure upon the Society's officials, plants for certificate cannot be entered on the morning of the show.

— LONGFORD HALL CUCUMBER.—The raiser of this variety, Mr. Barkham, Longford Gardens, Isle of Wight, was doubtless much disappointed that his Cucumber samples of some forty-eight fruits, shown at the Drill Hall on the 11th inst., met with no recognition at the hands of the Fruit Committee, especially after the same variety had but a few days previously been at Ryde awarded a first-class certificate. Possibly Mr. Barkham was, because of that award, induced to take so many fruits to London on the 11th; but the samples, though apparently thought much of in the Isle of Wight, were, as shown at the Drill Hall, a long way below London mark. Really, they were of the kind seen plentifully enough some twenty to thirty years ago, but have a long time been displaced by other examples. Country societies may not know this, and therefore leap hastily to conclusions. That the variety is a good cropper there can be no doubt, but so also are many others that produce fruits greatly superior in appearance.—A. D.

— HORTICULTURAL CLUB.—The usual monthly dinner and conversazione took place on Tuesday last. The chair was occupied by Sir J. T. D. Llewelyn, M.P., and there was a good attendance of members. A paper was read by Mr. Geo. Paul on the subject of *Amaryllis*. He entered at some length into their history and method of cultivation. He questioned whether a mistake had not been made in endeavouring to get the broad form of flower instead of the long tubular form of *Lilium longiflorum*, and thought perhaps something might still be done in that direction. Their slowness of increase militated against their more general cultivation. An interesting discussion followed, in which many of the members present participated. Considerable surprise was evinced at the statement of the Secretary, that he had had the hybrids of *vittata* raised by the late M. Souchet growing and flowering in the open air for the last twelve months; they were planted in the same situation as *Amaryllis Belladonna*, in a border in front of the greenhouse facing south, and passed through the severe winters which we have had lately without injury. A cordial vote of thanks was proposed by Sir John Llewelyn to Mr. Paul for his valuable and interesting paper, and was carried with acclamation. We hope to give the paper in a future issue.

— THE VICTORIAN ERA FUND.—Mr. R. G. Waterman, Secretary and Treasurer of the Mutual Improvement Society, Woolton, Liverpool writes:—"The Committee of the Liverpool Horticultural Association has placed at the disposal of the Woolton Society space at the forthcoming Exhibition at Sefton Park, to be held on July 31st and August 2nd, for the purpose of arranging a stall for the sale of plants, fruits, and flowers in aid of the above Fund. Could not this suggestion be generally followed at horticultural exhibitions and Rose shows throughout the country? This would prove the means of adding materially to the Fund, at the same time adding to the pleasure of the visitors to flower shows, especially in the vicinity of large towns."

— THE ROYAL KEW FUMIGATING COMPOUND.—By the use of the above compound for destroying various kinds of insect pests on plants and trees, both labour and expense have been reduced to a minimum. The old-fashioned way of fumigating with tobacco paper two or three times in succession to destroy such insects as green fly or thrips, is now with me a thing of the past. There is no injury to foliage or delicate blooms, such as *Calceolarias*, or *Cinerarias*, or *Orchids*, and all may be kept perfectly clean after using the compound. I find on referring to past accounts for fumigating material the cost is less than half what it used to be. We are indebted to Messrs. Timothy and Sandwith of Bracknell for advertising this most valuable article, which I find does all that the proprietors claim for it.—F. J. THORNE, *Sunningdale Park*.

— SEEDLING VIOLAS.—Some time ago an article appeared in this paper advocating seedling *Violas* in preference to named varieties for hedding purposes, one of the principal reasons advanced in their favour being earliness to flower, and further that they would invariably come true from seed. Having grown *Violas* by the thousand, both named and seedlings, I doubted the assertion at the time, but preferred to wait the flowering of a large number of seedlings this season before carrying the question further. So far as my experience is concerned, my previous opinions are fully confirmed. A recent visit to the charming public gardens of Guildford Castle still further proves that seedlings cannot be relied upon to produce a good uniform display of colour. A large bed containing several hundred plants is in full flower near the entrance. From a distance the effect is undeniably charming, but on coming closer the pleasing appearance is very much marred. Plants of many different habits in growth, flowers of all forms and colours, such as would turn a florist away in disgust, and out of the entire bed there was only one plant which would pass as a decent bedding *Viola*. Is such a result desirable? and what a contrast a bed of one or two named forms, such as *Blue Gown*, *Sylvia*, *Ardwell Gem*, *Goldfinch*, or *White Duchess*, would present. In conclusion let me say a word of praise for the skilful and courteous superintendent, Mr. Saunders. The general neatness of the grounds and surpassing quality of other spring flowering plants at once dispel any doubts about cultural skill being wanting in the *Violas*. It is too evident that seedlings are not the best for his purpose.—M. BAXTER, *Woking*.

— THE CRYSTAL PALACE FRUIT SHOW.—That it should be needful for the Secretary of the Royal Horticultural Society to make so strong an appeal for subscriptions to the customary £100 guarantee towards this great Fruit Show is essentially painful, yet apparently it is unavoidable. The demands made on every hand this year for pecuniary help, the wholesale haggling and cadging that under the guise of long reign commemorations is being resorted to in every direction, is beyond all precedent, and is doing much to cut the throat of true charitable inclinations and objects. That fact, no doubt, renders the getting in of ordinary subscriptions to useful and legitimate objects exceedingly difficult, and in many cases impossible. In the case in question, whilst something is asked for the promotion of national fruit culture, surely a patriotic object, very much is offered to every subscriber in the shape of a splendid show, whilst to a large number there is the prospect of a good return being made in the form of tangible prizes. For this latter reason both previous and intending competitors should contribute something. Then the Fellows of the Society, some 3000 in number, all of whom can see the Show without charge, might contribute something, if but small sums. Very large numbers of these will turn up at the Temple Show. Why not put up in prominent places collecting boxes, labelled "Silver collection for the Crystal Palace Fruit Show Fund?" Possibly a good round sum may be obtained in that way. It is not every one who can give a guinea, but thousands might give shillings and half-crowns. The comparatively small balance left after meeting last year's expenses hardly justifies the Society in holding the Fruit Show minus the required pecuniary guarantee.—D.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION. — We are requested to state that the fifty-eighth anniversary festival in aid of the funds of this Institution, will take place on Wednesday, May 26th, at 6.30 for 7 P.M. (the first day of the Temple Flower Show), at the "Hotel Metropole," under the presidency of the Rt. Hon. Lord Rothschild. As a large gathering is expected on the occasion, the Secretary, George J. Ingram, 50, Parliament Street, London, S.W., will be greatly obliged if those friends who desire to be present will intimate their intention to him as early as possible, so that the necessary arrangements may be made.

— FLORAL DECORATIONS AT CHELTENHAM. — During the recent visit of the Prince and Princess of Wales to Cheltenham the decorations at Messrs. Cypher's nursery were, as might be expected, very beautiful. On each side of the road a column had been erected in a very novel manner, at various stages of which towering Palms and foliage plants lent enchantment to the view, a splendid pair of *Phoenix rupicola* adorning the top of the columns. A basket of Orchids presented to the Princess of Wales was much admired. It contained some grand spikes of *Odontoglossums Alexandræ* and *cirrhosum*, also lovely sprays of *Oncidium obryzatum majus* and *Cypripediums Rothschildianum* and *grande*, and a few grand *Cattleya Mendeli* and *Lælia purpurata*, arranged with long sprays of *Asparagus*.

— JUBILEE FLOWER SHOWS. — I have no doubt because so early in the season there will be few flower shows held on June 23rd, but I observe with regret there will be two considerable ones near London—Richmond and the Crystal Palace. The former is held a few days earlier than usual, the last Wednesday in June being its ordinary fixture. The latter show is a special commemoration show. But great flower shows cannot be constituted by mere strokes of the pen, or the issue of schedules. They entail an enormous amount of work in the preparation of the material composing them, and in loading and carting. Now, it will be impossible for these two shows, both so needlessly held on the day following the Jubilee Bank Holiday, to be constituted without entailing upon a very large number of men in nursery and private gardens a hard day's work on the very day set apart for a national holiday, because of the Jubilee celebrations all over the kingdom. Why should not some consideration have been shown towards all these people? Why compel them to work when they would prefer to be taking part in holiday functions with the rest of the community? The arrangement seems to be a very selfish one. That because of the difficulty likely to arise in securing vans on the Jubilee Day, great obstacles will be placed in the way of carrying plants long distances, there can be no doubt. That is, however, a matter for those who organise shows and exhibitors. In many cases furnishing plants, of which so many groups are now composed, will be required in other directions, and Roses may be expected to be cut to the last flower for Jubilee decoration.—D.

— NEW CORN PRODUCT. — The discovery that the pith of the corn stalk can be used in the construction of war vessels is likely to be of benefit to agriculture in more than one way. The chief use of this pith is for a packing between the inner and outer shells of the vessel, so that when pierced by a projectile it will absorb water and swell so rapidly as to close the opening before the vessel leaks to a dangerous extent. Experiments with this pith have been so satisfactory, says the "Garden and Forest," that it has been adopted in the construction of American vessels of war, and European nations have commissions for investigating the same material, so that the use of corn pith will make a market for what was once a waste product. In the process of extracting this pith the blades and husks are removed, and the stalks are cut into small pieces. When the pith is taken out from this stalk, the remainder is ground up into a flour-like substance which resembles bran. Some experiments with this "new corn product," as it is called, have been made at the Maryland Station, with the remarkable result that it is found to contain 11 per cent. more of digestible matter and 2 per cent. more of digestible protein than the whole fodder does when shredded. It does not contain as much digestible albuminoides as Wheat bran, but it equals that food in the total amount of digestible matter. It keeps as well as bran or Cotton-seed meal. It is in such condition that it can be uniformly mixed with any ground grain, and when used as a base it is possible to make a complete and normal ration for stock in one bulk without the necessity of feeding grain and hay separately. Animals fed upon such a ration eat it with relish, and keep in normal condition. Since there is only 1 lb. of pith to 14 lbs. of blades, husk, and stalk, this new material amounts to a very considerable portion of the fodder.

— FLOWERS AT CHELSEA. — At all times of the year flowers are to be found in the famed nursery of Messrs. James Veitch & Sons, but at the present time the display is more than usually imposing. One large house is such a mass of floral beauty as is rarely seen—*Liliums*, *Azaleas*, *Heaths*, *Spiræa astilroides*, in fact almost all greenhouse flowers of the season contributing to the display. In another house is a rich floral feast of *Gloxinias*, and many new forms of *Streptocarpus* of an interesting and attractive character evoked admiration.

— READING COLLEGE. — The fourth supplement of the Journal of the University Extension College, Reading, has reached us from the Agricultural Director, Mr. D. A. Gilchrist, B.Sc. This report deals with the field experiments that have been carried out by the College in the counties of Berkshire, Dorsetshire, Hampshire, and Oxfordshire during 1896. Besides these there are articles on manures by Mr. Gilchrist, and a report on injurious insects by Mr. P. H. Foulkes. The book contains much matter that would prove interesting to cultivators of the soil, more especially farmers, and it may be obtained from the College for 6d.

— "THE COUNTRY GENTLEMEN'S CATALOGUE." — A copy of this book for 1897 has just reached us from the publishers, Messrs. Eden Fisher & Co., 32, Mitre Street, London, E.C. Including the advertisements the catalogue comprises upwards of 220 pages, and is clearly printed on good paper. Almost all departments of sport in which gentlemen take an interest are referred to more or less briefly, while notes relating to farming are plentiful. Chapters on manuring land, feeding, and dairying should afford valuable hints to soil cultivators, and the list of agricultural shows is complete. The price of the book, which is strongly bound in red covers, is 3s. 6d.

— PRUNUS DAVIDIANA. — The first tree with conspicuous blossoms to flower this year in the Arnold Arboretum was the North China Peach, *Prunus Davidiana*, which has been extraordinarily beautiful. This tree is perfectly hardy, but the flowers are often killed by frost after the buds begin to swell, and during the ten or twelve years that it has inhabited the Arboretum it has only once or twice before flowered as profusely as it has this spring, and although producing more or less flowers every season, it has not borne fruit yet in the Arboretum. According to a transatlantic contemporary *P. Davidiana* ought to be better known as an ornamental tree, as it flowers before any of its kind, and the pale pink petals, although not as large as those of some forms are exceedingly attractive. The culture presents no more difficulties than other *Prunus* more generally grown.

— MAPLEWOOD. — Maplewood has a distinct and positive value for flooring which no other hard wood which is workable possesses. Its hardness and smoothness give it power to endure the severest wear; it has a light and attractive colour, and it can be cleaned as easily as Maple. It has hitherto been abundant enough to meet the growing demand in every part of the continent and the requirements of the large export trade. Nevertheless, since only a part of the tree is utilised, the waste of the lumber is great, and the best hard Maple, which is found in the lower Michigan peninsula and in Wisconsin, is disappearing more rapidly than even the Pine did, because, as a rule, good Maple land is good farming land. The time seems to be coming when the supply will be depleted, and the "North-Western Lumberman" is, no doubt, right when it complains of the reckless competition under which this valuable product is sacrificed.

— WOOLLY APHIS. — Although I cannot tell your correspondent Mr. Hiam, page 388, why woolly aphis is called American blight, I can tell him something more useful—viz., what will kill it. In most old gardens a few gnarled treasures of Apple trees are to be met infested with woolly aphis (American blight). The owners prize these old stumps so much that it is considered little short of sacrilege to touch a twig of them. Such trees become nurseries for producing and distributing the pest. This state of matters can now, however, be remedied with the use of "Spidacide," a new product of exceptional merit, which every gardener and fruit grower should know. Last autumn we applied it with a syringe at the strength of half a pint to the gallon of tepid water to some trees then white with woolly aphis, with the result that every insect, so far as we could tell, was killed, and not a leaf injured. This efficacious insect eradicator cannot be too well known.—J. RIDDELL. [If this new product, recommended so highly by a practical man, is manufactured for sale, it can be made known in the usual manner by which other useful products have found their way into gardens all over the kingdom.]

— "MAKING MORE GARDENERS."—This heading to a paragraph in last week's issue doubtless conveyed to some readers' minds the impression that the writer thought there were too many gardeners made already. Really it does seem as if the vocation in relation to work was already greatly overdone; indeed, requests for assistance to secure situations become painfully frequent. But, farther, the paragraph itself naturally leads to wonder what sort of gardeners are likely to be turned out from the Royal Botanic Gardens. Possibly the youths finally selected for the L.C.C. Scholarships will think themselves fortunate, and if these Scholarships were to be worked out in some practical garden I could think so too. But the Botanic Gardens are partly of a botanical order and partly of a pleasure order. Young men may learn to grow plants in houses, and something of the orders, species, and parts of those inside and out; they can learn to mow and sweep, to weed and roll walks, to bed out, and generally keep pleasure grounds neat and tidy. But with regard to the far higher and more important work involved in fruit and vegetable culture in and outdoors, can they there learn anything? I fear the outcome of even three years of such training will be very disappointing. After all there is no place for a youth to learn gardening in like a good class private garden, where practically every department of gardening is exemplified. If after a few years in such a place he can get a couple of years in a nursery in departments, and a year in a good market-growing establishment, then he would have first-rate opportunities for gaining knowledge of the most useful kind.—A. D.

PLANTS IN HOUSE DECORATION.

THE grouping of plants in a miscellaneous manner, or even using one variety to form a group, seems to be inadmissible and out of character with artistic surroundings of saloons and reception rooms. But even to this rule there are exceptions, as the broad landings of a double staircase where each side might be flanked with plants with an appropriate edging; or perhaps the extreme end of a suite of reception rooms on a raised buffet, so that the lowest plants in front are not much below the line of vision. These groups should not be in any way formal, but light, graceful, and elegant; the buffet or cellarette ought to be hollow and lined with zinc, so that the water falls below, and to allow of it being emptied. No pots should be in sight, and fresh or artificial green moss must be used to cover naked surfaces. The front should be draped with trailing plants.

In these groups flowering plants possessing beauty of form ought to be arranged thinly enough to show their curvature and grace to advantage, and those distinguished for purity, intensity, and brilliance of colour in a mass, for if Nature pleases us with her forms she enchants us with her colours. These groups will perhaps be best confined to one variety of plant, excepting the drapery. If gradation of colour is attempted it must be as a reflection—a bright colour at the back leading to some simple shade in the front; but dominant harmony as shades of one colour must be avoided, contrasts and analogous harmonies being most pleasing.

By the latter term is meant relative hues, as shades of colour formed by the combinations of red and blue—as crimson, rose, and purple, or shades of red and yellow in combination—as scarlet, orange, and salmon. In the class of plants possessing beauty of form may be put Callas, Poinsettias, deciduous Calanthes (rising from greenery), Lilliums, Francoa ramosa, Gladiolus The Bride, and so on. Beauty of colour may be represented by Azalea indica (semi-double), Azalea mollis, and most hardy forced plants, and Zonal Pelargoniums. Jardinières on mantel-pieces in front of mirrors should be filled with plants of the very lightest elegance, Cyperus alternifolius, Celosias, Rivina humilis, Freesias, Roman Hyacinths, or Pilea muscosa. Mirrors in corners having shelves in front to hold vases are very pretty draped with Panicum.

But what adds to the artistic furnishing of the rooms are the plants that stand alone, conspicuous for their grace and beauty. These must always be faultless specimens, and the vases containing them should stand on pedestals, so as to raise them up within the line of sight, or above it. The tops of pianos are now mostly loaded with flowers, and beautiful flowering plants are sometimes used. The plants standing in window recesses, excepting Palms, should be flowering or bright hued foliage plants. Yellow is the colour for windows, as it is like transmitted sunlight. Yellow is also the colour for dark or badly lighted rooms.

The plants for boudoirs are mostly flowering ones of small size, and preferably sweet scented. From rooms in which the wall coverings, window hangings, and carpets are of green or sea green all blue shades must be excluded, and where the prevailing colour in the room is blue the purples, crimson, rose, and a great many other shades will have to be excluded.—F. STREET.

BIRMINGHAM NOTES.

A RECENT look in at that popular Midland horticultural resort—the Botanical Gardens, Edgbaston, disclosed several specimens worthy of note, as for instance a good display of *Spiraea arancus astilboides*, with its elegant, creamy-white coloured plumes of inflorescence. Attention was also drawn to another denizen of the greenhouse, *Streptosolen*

Jamesoni, erroneously formerly called *Browallia Jamesoni*, large plants covered with rich orange coloured short trumpet shaped blossoms; also in close association with the preceding was that uncommon hard-wooded plant, *Ochna multiflora*, with its small pendulous parti-coloured flowers. Not the least attractive was a display of several of the leading varieties of both "show" and fancy Auriculas, arranged around the centre stage in a cool house, whilst in a contiguous apartment a rich and large assortment of Gloxinias was noticed. Gratifying also was it to observe the flourishing condition of the occupants of the Palm and Tree Fern house, unfolding their attractive bright green fronds.

Apropos of Ferns, Mr. Latham ventures an assortment of Filmies, including *Hymenophyllum tunbridgense* and *Trichomanes radicans* growing in close association with one or two species of Todeas, all in a state of luxuriance. The comparatively few Orchids in flower at the time of my visit claim some little notice, especially with regard to a small plant of *Angraecum modestum*, with a fine single raceme of its pure white, chaste looking inflorescence. A healthy piece of *Cochlidia Noezliana* was represented by several spikes of its uncommon and attractive flowers, deep rosy coloured; whilst *Cattleya citrina*, *Cymbidium Lowianum*, *Phaius Wallichii*, *Coelogyne elata*, *Masdevallia chimera* var. *Wallisi*, *Cypripedium barbatum*, *C. Lawrenceanum*, *Dendrobium thyrsiflorum*, *D. infundibulum*; *Odontoglossums Pescatorei*, *cirrhosum*, *Rossi majus*, and *crispum* were also conspicuous. These were supplemented by large specimens of the gaudy *Anthurium Scherzerianum*, which does not fail to attract the most unobservant of visitors.

In the outdoor department, where order and neatness, as usual, prevail, unfolding vegetation proved attractive, including the developing inflorescence of the denizens of the alpine rockery garden, though owing to the recent prevailing abnormally cold weather these charming heralds of the summer have been somewhat retarded. We may observe, in conclusion, that Mr. Latham evidently purposes promoting an increase of that hardy evergreen Bamboo, *Arundinaria metake*, by reason of its persistent evergreen and elegant foliage, affording such a pleasing relief, especially during the winter months, to the surrounding deciduous trees and shrubs. Surely an extended recognition and cultivation of these elegant hardy exotics is most desirable in this country for the embellishment of our shrubberies.—W. G.

THE SCHOOL GARDEN.

CONTINUING my remarks from page 384 on the subject, it may be well to point out that the District Councils are empowered to provide allotments for farm labourers, and doubtless also for land intended for school gardens. Then with regard to the Education Code, "Elementary Agriculture" and "Plant Life" are both named on the schedule of class subjects, and when, according to H.M.'s Inspector, they are successfully taught in accordance with the regulations, a sum of 2s. per head is allowed on the average attendance.

By the term "school garden" is not meant merely a small plot for flowers adjacent to the school premises, though even such a provision would form an interesting and useful adjunct to the country school. My idea of a school garden is that every school in a rural district should have, as conveniently accessible as possible, a piece of land large enough for the purpose. The area, of course, would not only depend upon the extent at disposal, but upon the staple and quality of the soil, and upon the physical ability, intelligence, and industry of the young tenant. The boys of standards IV., V., VI., only should be eligible as tenants, but the lower standards ought to have access to the gardens under proper supervision, for the purpose of object lessons and watching the process of the work of the older boys. Each plot should be cultivated by the tenant holding it, under the guidance of the teacher, whether the school-master or a neighbouring gardener called in at stated times to assist for a few hours weekly in directing the work.

It appears to me to be essential to success that the land and the implements employed in its cultivation should be furnished free of expense by the managers, and that no charge should be made any more than for the use of the schoolroom, books, pens, and paper in ordinary teaching. They should be regarded as an outdoor class-room. The time employed in the garden should be at least three half-hours weekly, another three half-hours being spent on lessons and book work on the subject indoors. Each boy should be required to keep a logbook, which should contain entries of cultural operations, digging, sowing, planting, hoeing, watering, and gathering crops. Careful accounts should be kept of the smallest item of expenditure, the time spent on the garden and the kind of occupation, the money expended on seeds, plants, or manure, parts of crops taken away for use at home put on the creditor side at market value. In one set of school gardens boys of eleven years have been known to make a profit of 12s. in a year on a plot of six poles.

A small amount of space might be devoted to flowers. It is needless to enlarge upon the advantages accruing from such a delightful recreation. It may be well, however, to take note of the fact that the sale of flowers and roots is now a large and increasing trade. Flowers, which half a century ago were regarded as a luxury, are now an apparent necessity. Moreover, the encouragement of flower gardening among cottagers' children, apart from its refining influences, is not infrequently a welcome addition to the family income.

A plot of eight or ten poles in extent might advisedly be set apart for a trial or experimental garden, in which the quality of seeds and manures might be tested with different modes of cultivation, as it must not be forgotten that the majority of the sons of small farmers receive their only education at the village school.—HERGA.

ROSE SHOW FIXTURES FOR 1897.

- June 7th (Monday).—Cambridge.
 „ 9th (Wednesday).—Chelmsford.
 „ 15th (Tuesday).—Ryde.
 „ 16th (Wednesday).—York.†
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 23rd (Wednesday).—Richmond, Surrey.
 „ 24th (Thursday).—Colchester.
 „ 25th (Friday).—Maidstone.
 „ 26th (Saturday).—Windsor and Dorking.
 „ 29th (Tuesday).—Canterbury, Hereford, Sntton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon, Ealing, Farnham, and Reading.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells
 „ 8th (Thursday).—Bath, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.
 „ 13th (Tuesday).—Wolverhampton.†
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 17th (Saturday).—New Brighton.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.
 „ 28th (Wednesday).—Chester.*
 „ 31st (Saturday).—Liverpool.*

* A show lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

COMMENTS AND IMPRESSIONS.

DURING the twenty years that the *Journal* has furnished me with abundant instruction and entertainment week by week, the Rose pages have always been eagerly and closely read, greatly to my advantage in the early struggles to overcome difficulties connected with successful culture. Rarely have I contributed my experiences, however, probably from a consciousness that it is not easy to write anything fresh upon a subject which has been so ably and fully treated by the veterans of the Rose world. Still the *Journal* writers seem to be united in such a close brotherhood, and the Editor so frequently encourages his readers to add to the common store, that it becomes almost a duty to help, with the hope that such hints as may be given will assist someone starting on the "thorny" path. That is one of my objects, but I may now and then take a step in advance; and if this first letter pass safely through the preliminary ordeal and reach the world of readers, as is hoped it may, I shall feel emboldened to try the experiment again.

Some time since I was talking with a friend of horticultural proclivities who has courted the favour of many flowers, each of which has possessed his mind with the greatest enthusiasm in turn, and he confessed very earnestly that, notwithstanding his seeming fickleness, his true love is the Rose. Solemn vows were made, too, that he would prove his loyalty to the queen of flowers by again entering the fateful arena of show competition. There are many flower lovers like my friend, whose hearts are large and whose admiration for Nature's most charming productions is unbounded, and yet there is some one flower which has the chief place and retains it against all others. With regard to the Rose, the great and enduring quality is that its charms are ever fresh; it is like a valued friend whose depth of character we have fathomed, and whose merits have been proved. Even though it possesses some of the characteristics of the gentler sex in regard to the fact that it is "uncertain, coy, and hard to please," yet we reap ample reward for devotion in our fair queen's smiles when we watch the exquisite beauties of the developing flowers.

Perhaps these thoughts have been suggested by a morning inspection of my Roses, which has brought to mind the working and watching of many years, their attendant disappointments or happy realisation of wishes. It brought back memories, too, of the early days when, after initiation into the mysteries of budding, I watched with pride the development of the buds which had "taken." Since then I have budded, grown, and studied many thousands of Roses; but it is questionable if keener pleasure has been derived from any than was afforded by these first exploits.

The satisfaction of being able to cut bountiful baskets of delicious blooms for home use or friends is indeed great; so, too, the rosarian's heart warms at the sight of the "first prize" secured to a stand of flowers at a show. But the memories of early floral triumphs, young though they were, are more lasting, because the impressions were made when the mind was more plastic and experience restricted. It is the same in many other things, for I remember on one occasion having a

most entertaining conversation with the late Dr. Hogg on a similar subject, and he related with much gusto the following anecdote:—In preparing one of the earlier editions of the "Fruit Manual" for the press he found that he had not included in it an Apple which was well known to him in Scotland, and remembered from his boyhood's days as possessing an exquisite flavour. Diligent search amongst the fruit collections in the South failed to reveal this wonderful variety, and the Doctor undertook a journey over the border mainly with a view to its rediscovery. It was indeed found. "But," said he, in concluding his story, "never was I more disappointed in my life, for the Apple proved to be a flavourless, useless variety, greatly inferior to hundreds known to my later years."

Much the same might prove to be the case with regard to the Roses and other flowers of early youth, difficult though it seems to realise. Certainly my memories of the Roses which adorned the country garden in my boyhood's home represent them as superior in most respects to any I have been able to grow since. Arbours and arches were draped and festooned with profusely flowered and varied climbing and trailing Roses, while the Roses in beds cut in the grass appear to have been so rich in colours and fragrance, and to have afforded so long a succession of handsome flowers, that my best efforts have never enabled me to reproduce. One of the old favourites, however, may be cited as an exception, the good old Général Jacqueminot, for this at least is fully up to memory's standard, and is even now one of our most valued Roses of its class and colour—speaking from a garden rather than an exhibition point of view, though blooms are still seen in leading stands. Another which I remember well as especially handsome was Cramoie Superieure, but though I have had a variety under this name several times it has never seemed to approach that in my mind. Some of these old Roses are delightful garden plants, and without attempting to classify them we may set down as examples of those for beds the old China, Fellenberg, and Aimée Vibert, while as climbers there are numbers which are most floriferous. It is after all as a garden plant that the Rose must have the greatest number of admirers, and while fully recognising the interest and help derivable from the shows it is yet in the garden, however pretentious or humble it may be, that we secure the greatest pleasure from our favourites.

Occasionally if the Editor deem my contribution of sufficient value, I shall hope to refer to some of these old Roses more particularly, to state my experiences and observations with the more recent varieties, to comment freely on Rose gardens and exhibitions, and to give such cultural hints from time to time as may be seasonable and of general interest. As this is only a preliminary letter which has extended somewhat beyond its intended limit, I can only now say that a cultural topic to which my first notes will be devoted is respecting the use of artificial manures as partial or entire substitutes for stable or farmyard manure. Here I shall probably be disturbing the Rose growing traditions of many, but what I have to record is simply the result of my own experience, and must therefore be taken on that basis. It had long been my belief that in some soils a large amount of stable manure was not merely unnecessary for Roses, but positively hurtful to certain varieties, and I determined to endeavour to ascertain how far some of the simpler chemical manures could be employed with advantage as substitutes, while obtaining the required vigour of growth, substance of bloom, and clearness of colours. Though there is much more to investigate some interesting results have been observed, and are at least suggestive.—MIDLAND ROSARIAN.

[The insertion of these notes is the best evidence of their acceptability, and our correspondent can, if he can find time, contribute much that is interesting, suggestive, and useful pertaining to the Rose.]

CONSERVATORY MANAGEMENT.

SUPPLEMENTARY to my notes in the issue of April 1st, page 280, I send the following account, together with a photograph of the conservatory at Walton Lea. The house is 40 feet long by 25 feet wide. At the west end, or that which is represented as most distant in the picture, is a fine specimen Camellia of the alba plena variety, with smaller plants on each side of it of Donckelaari. Borders about 4 feet wide run along each side of the house, in which the climbers are planted, and on which plants are also arranged.

On the centre floor are arranged three groups similar to the one seen in the foreground of the picture. At the time of photographing the house was furnished chiefly with Azaleas, Dautzia gracilis, and other miscellaneous plants. Of the former the following are among the varieties grown:—Duc de Nassau (of which there are several fine pyramidal plants 7 feet high and 4 feet through), Souvenir de Prince Albert, Stella, Model, Baronne de Vriere, Duc de Brahan, Mdle. Marie Planchon, B. S. Williams, Dr. de Mill, Bernhard Andreas alba, Apollo, Sigismund Rucker, Balsaminiflora, Madame Van der Cruyssen, and others.

It may interest the readers of the *Journal* to know that this house, as well as the other plant and fruit houses, are open to the public of the neighbouring town of Warrington twice each year (two days on each occasion)—in the spring for the purpose of viewing the Azaleas or Camellias, in the autumn for seeing the Chrysanthemums respectively. On these occasions visitors to the number of several thousands attend the gardens. Special arrangements are made to facilitate their passage through the houses and grounds. These show days are looked forward to with great interest, and the privilege accorded is highly appreciated.—P. W.

INSECT INVASION.

I AM struck (neither dumb nor unable to write, thank God) by a few words in "W.'s" reply to the "distressed correspondent" suffering, as who does not at this season, from insect invasion. The lines are these:—"A shilling spent in insecticides early in the season, and the powder or solution applied when the first insect is seen, or, what is better, *before as a preventive* (the italics are mine), will effect the purpose far better than can be accomplished by an expenditure of 20s. after the shoots are crowded with aphides."

The distressed correspondent does not state what insect. Of course, he or she ought to know that eggs laid in the autumn, as the sun in April and May warms them, hatch, and the influx begins. This time, as "W." rightly says, is the time for action, "or before." Now supposing then the pest to be aphides, what can we do *before*? Cleanliness everywhere is a help, but in greenhouses it is not a time of year when you

without examining *why* it is so; the enemy will not be found in nine cases out of ten on the upper surface of the leaf, but underneath. This fact is one of the difficulties in applying liquid insecticides—it does not reach the enemy.

In the house the presence of a few aphides should be the signal for immediate fumigation. Personally, I have found nothing to equal the XL liquid for vapourising. I have no interest in recommending it, other than to assist "distressed correspondents" in repelling the attacks of the aphids tribe, but if the directions are strictly followed nothing, in my hands, has been so safe, so effective, and so lasting as this. Lately a friend came to my house, to whose gardener I had given some plants, and the latter, remarking on the cleanliness of my Cinerarias, complimented me. I gave the credit to the XL, where indeed it was due. "Oh!" he replied, "the master will not use it, it is so awfully expensive." So to the master I asked why he did not use it, and his reply was that his last gardener used a 13s. bottleful for one house! This, I

FIG. 88.—CONSERVATORY AT WALION LEA.

can turn out your plants and scrub and clean, but this might be done later in the autumn. Will that rid us of green, brown, blue, and black aphides? I trow not. What are the eggs of the aphids like? I, to my knowledge, have never seen any, and it strikes me they must be very minute; but after all, as far as the aphids is concerned, were it only by eggs hatching that these pests arrived, they would be fewer by myriads than they are now. Like the poor, the aphids in its varied forms "we have always with us." It is the rapid increase that the female aphids after hatching is capable of by that process of disbudding from itself perfect females, equal in a few days to the same process or function, that covers our plants so speedily, and that permits according to the naturalist Reaumur, who watched them so attentively, the female to be the great great grandmother of these myriads during her own lifetime. The process is continually going on, and it alone accounts for the rapidity with which a shoot that has a female on it to-day, may in a few days be literally swarming. The verdict is—do not spare the first you see, eye, and look for them. Never see a curled or crumpled leaf

am quite certain was not following the directions. Can it have any effect on the eggs? Being an ignoramus, I hazard this question. From the lasting effect of this compound I am tending towards the possibility of this; if so, it is an additional reason for using it, for we then come to an application of a remedy before the pest appears, which is a great desideratum, and the point which struck me in "W.'s" remarks. I expressed this opinion to a gardener to whom I had lent the apparatus, and he replied, "Well, I must say that our house has never been so free of aphides as since I used it."

But when we leave the house and come to the open, the enemy is much more difficult to conquer. We cannot use XL. The old saying is, that "the master's eye is worth two pair of hands." Both eyes are needed to see the first visitor of this legion of persistent enemies. Any curled or crumpled leaf on Peach, Pear, Plum, or Apple, or in fact any tree, is a warning. Pick it off and open it, and possibly a family of them will reward the search. I syringe my Peach trees daily, in the morning. I fancy it a help, but when the leaf is curled up I doubt

much reaching the enemy; but it often brings down the crumpled leaf, already weakened by the attack of its foes, and these leaves should be picked up and carried to the fire. At the same time I pick off every blistered leaf, and let them share the benefit of the great destroyer—fire. I doubt sometimes by the appearance of these leaves that there are spores that may spread the trouble. A diseased leaf is no help to the tree, but both a dis-sight and a spreader of mischief. Shoots that are covered with aphides may be bent down and shaken in quassia or tobacco water, or powdered with the powdered tobacco; but out of doors the watch must be incessant and the remedy prompt.

Then how many ignorant persons fond of their garden kill their best friends. The tits are very fond of aphides, and though I cannot say much for the sparrow, I have seen him dining off aphides, or else my eyes deceived me; but few know by sight their insect friends who live on the aphids. The ladybird is well known in its mature state, but possibly only when red, but the black-and-yellow small varieties are equally useful. But if in the beetle stage it is recognised, how many persons know it in its larva state when it is most useful? Then it somewhat resembles, except that it has six legs, a tiny lizard with a short, thick, dumpy tail instead of a long one. Perhaps in the pupa or chrysalis state, as it does not move, and looks only a black spot, it escapes detection, and so is saved, but if seen I fear is often squeezed and put out of the way.

The larva of the lace-winged fly, the lion of the aphid tribe, is generally sharp enough to save himself and drop out of the leaf, and then these, alas! are not very common; whilst the larvæ or grubs of the syrphus flies, which would nearly clear a twig in a night of the aphid host, pays the penalty of being like a green grub, and is often ruthlessly destroyed by the ignorant as a good deed! Had I as many of these friends as I wanted, all other insecticides as far as regards the aphid I could dispense with; they do their work expeditiously and perfectly. To the uninitiated I can only say that if they see in the neighbourhood of aphides a grub which, when it moves, has a pointed head, it is probably one of these, and worth to the gardener its weight in silver, I think in gold.

The Cherry aphid is black. Tackle it early or the ends of the growing shoots will be as black as soot, and soon the stems of the young fruit will be black also; if then the remedy is not quickly and effectually applied the crop will be ruined.—Y. B. A. Z.

STRAWBERRIES AT KNOWSLEY HALL.

THE forcing of Strawberries is carried out in the majority of large gardens with the best possible results, but I can safely say that nowhere have I seen better than those at Knowsley, where Mr. Doe, Lord Derby's gardener, has a show worthy of the highest possible commendation. Last season they were more than fine, but I was little prepared to see the great advance made this year. One shelf, with 200 plants in 6-inch pots, each carrying from nine to a dozen fruits just ripening, was a picture, and on all sides plants in various stages were to be seen. The greatest treat, however, was left until the last, when I was taken into a three-quarter span-roofed house containing four rows of plants on the front stage and three rows on the back. The leaves were of a deep glossy green, and the fruit large, many weighing 3 ozs. each, and of an intense scarlet. In all there were 300 plants, each carrying about nine large fruits, and all thoroughly ripe.

Apart from their usefulness the house presented such a charming appearance as to baffle description, and it would have been idle to suppose that such results could have been obtained without the aid of judicious thinning of the fruits and careful feeding with artificial manure. Another important matter must be kept in view—viz., the superiority of the newer varieties, as it would be utterly impossible to get such a weight of fruit from the older sorts. The variety I have tried to describe is Royal Sovereign, of which more than 2500 out of 4000 have been grown. Mr. Doe informed me that he could not think of growing La Grosse Sucrée again, and he intended growing 3000 of the former this year, relying on Monarch and Leader, as he is now doing, for the later crops.

That the preparation of the young plants is of the greatest importance goes without saying, and Mr. Doe is no believer in waiting for runners until the fruit is on the plants, and the difficulty increased tenfold. He is already prepared with plants from last year's runners, laid in beds, 6 inches between the rows. These lift with capital roots, and are at once transferred into their fruiting pots. Where sufficient runners could not be had other plants are growing in convenient situations for the early supply, the saving of labour alone being very great. In concluding I can only say that Mr. Doe's system is worthy of emulation, being sound and practical, and the results of the greatest excellence, not only creditable to himself but satisfactory to the noble family he serves so well.

Although only spending a few minutes at Knowsley I managed to get a peep into the handsome new conservatory recently erected. The painters were taking possession, but a small half-circular bed attracted my notice. In the centre stood an old *Cycas revoluta* with not an inviting stem, and to clothe this Mr. Doe had a *Clerodendron Balfourianum* planted and loosely twined round. As the *Cycas* was resting the shoots had been allowed to ramble at their will into the centre of the plant, the beautiful white and scarlet bracts looking delightful against the dark green leaves of the *Cycas*. It was all so natural that I could not refrain from noticing it. The remainder of the bed was filled with small dwarf *Ixoras*, which in their turn command much admiration.—R. P. R.

WEST OF ENGLAND CHRYSANTHEMUM SOCIETY.

THE schedule of this Society, which will this year hold its annual show in the Guildhall, Plymouth, on Tuesday and Wednesday, Nov. 2nd and 3rd, is divided into five divisions, besides which there are several special prizes. The principal class is for forty-eight Japanese blooms in twenty-four distinct varieties, the prizes being respectively £10, £7, £4, and £2. For a group of Chrysanthemums, interspersed with foliage plants, the sum of £21 is offered. The former class is open, while the latter is confined to the counties of Devon and Cornwall. Besides these there are many others devoted to the autumn favourite, besides several for fruits and vegetables. The Hon. Secretary is Mr. Chas. Wilson, 4, North Hill, Plymouth, to whom all applications for particulars should be addressed.

BAMBOO CANES AND EARWIGS.

I QUITE agree with "J. C.," page 362, as to bamboo canes being a harbour for earwigs. These pests, as is well known, are the worst enemies we have to contend with on Chrysanthemums. Last year they caused me endless trouble. They damaged every bud I had on two special plants of Madame Carnot, although a watch was kept for the marauders late at night and early in the morning. They seem to heartily appreciate the beautiful variety named.

I like to buy bamboos in four sizes—6 feet, 5 feet, 4 feet, and 3 feet lengths, thus saving time and waste in cutting large canes. The first wet day after receiving them I have them plugged with rather stiff "putty," and well painted green within 4 or 5 inches of the bottom, according to size. If this is done some three or four months before wanted they get well set and hard. The canes should be pointed also at this period, and then all will be ready for use at a time when little of it can be spared.

I owe my earwig trouble of last season to Nut trees being rather too near, as I found they were full of pests. I at once moved them clean away from the spot, and little bother they gave me afterwards, so getting anywhere near Nuts must be shunned to the utmost.—R. BASSIL, Pangbourne.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE monthly meeting was held in the Society's rooms on Wednesday, the 12th inst. After the minutes of the previous meeting had been passed, the Secretary, Mr. W. Housley, read a letter from the Decoration Committee thanking the Society for their offer to decorate an arch on the occasion of Her Majesty's visit to Sheffield on the 21st inst., which they regretted they could not accept on account of previous arrangements whereby all the arches had been allotted to the Committees of the various sections of the route to be taken by the Queen. They would, however, be glad if the Society would decorate the Vestry Hall on the following day, the 22nd, in which the Mayor, His Grace the Duke of Norfolk, will entertain the aged poor. The invitation to undertake the decoration was unanimously accepted.

The monthly exhibits were herbaceous Calceolarias for professional members, and some excellent specimens were exhibited. The prizes were awarded to Mr. T. Garbry, first; Mr. Thos. Morton, second; and Mr. C. Shorten, third. The amateur members competed with three cut blooms, amongst them being some good spikes of Orchids, Amaryllis, Philo-cactus, and Roses. Mr. G. Walker obtained first, Mr. W. Willgoose second, and Mr. M. H. Willford third prizes.

The essay on the "Cultivation of the Dahlia" was then read by Mr. W. Willgoose. On a previous occasion the essayist, who read a paper on the storage of the tubers in winter, commenced his second part of the subject by beginning with the storing of the roots, taking off cuttings, and his method of growing the plants until ready for planting in the open ground. He also explained his method of preparing the beds, planting, growing training, and protecting the flower buds, fully explaining every process. The essay was a very instructive and exhaustive one, and left few questions to be asked. A good discussion followed, and the essayist was accorded the usual vote of thanks. Mr. Willgoose exhibited some good photos of his collection of Dahlias, taken last season when in bloom, also photos of a plant before and after thinning out the laterals. Mr. John Haigh occupied the chair.

PINE APPLE JUICE.—Some time ago a medical scientist noted that Pine Apple juice contained a proteid-digesting substance. No careful study of this fact was, however, made by him. Recently, another investigator has gone into the matter fully, and announces facts which are likely to give to the succulent Pine Apple a prominent place in dietetics. Pine Apple juice is an acid fluid of specific gravity of 1.043. An ordinary Pine Apple yields 600 to 800 cubic centimetres of it. The proteid-digesting power is quite remarkable in its intensity. Three ounces of the juice will dissolve ten or fifteen grains of dried albumin in four hours. The action takes place in acid, neutral, or even alkaline media, thus resembling trypsin more than pepsin. It acts best in neutral solutions.—("Science Siftings.")

BRIEF NOTES ON ALPINE FLOWERS.

(Continued from page 320.)

IONOPSISIDIUM ACAULE.

PURSUING my intention of drawing attention from time to time to some of the dwarf annuals adapted for the decoration of the rock garden I now seek to say a few words in favour of this little Violet Cress or "Diamond Flower," as our cousins across the Atlantic have named it. It is not a new flower, having been cultivated for many years. It came originally from Portugal, but has never found its way very widely into cultivation, although cheap and easily obtained from seedsmen. It is best treated as a hardy annual, and sown very thinly in the place where it is wanted to bloom.

Unlike many annuals it rather prefers a shady and somewhat moist position, such as may be found at the base of the northern or eastern sides of many rockeries. In such a place this little plant, growing only an inch or so high, with its fresh little green leaves and its tiny, but bright, violet flowers, is certainly a very attractive object. Not the least of its merits is the way in which its blooming is prolonged, not only far into autumn, but even into winter. The soil should be a little stirred before sowing, but deep loosening is not required, which is an advantage, as this little Violet Cress is often useful to occupy the space left bare by the decay of the leaves of shallow planted spring-flowering bulbs which it is undesirable to disturb. After sowing a sprinkling of soil ought to be put over the seeds.

SCHIZOCODON SOLDANELLOIDES.

This undoubtedly valuable acquisition to the number of our rock garden plants has been a remarkably long time in finding its way into catalogues. It was, as the description attached to the excellent figure in the Journal of April 15th (page 323) says, introduced from Japan in 1891, and surely long enough time has elapsed to permit of its finding its way in quantity to our alpine nurseries. It is offered at a low rate by Japanese nurseries, and, even allowing for a considerable loss in transportation from the land of the Cherry blossom and Chrysanthemum, ought to be had at a moderate price here.

I have been indebted to a reader of the Journal—Mr. A. K. Bulley of West Kirby—for a plant. Mr. Bulley is most indefatigable in his search for new plants, and one is safe in predicting that in a short time he will have one of the best collections of rare hardy flowers to be found in England. I do not know that anyone can yet say with confidence what treatment will best suit this exquisite little plant in any particular garden, but am inclined to think that a half-shady position in peat soil will be found answerable. The small, pretty leaves, so well shown in the engraving, are of a deep, yet bright, red colour. The flowers shown in the woodcut will prove to those who know the Soldanella how aptly this little Schizocodon has received the specific name of soldanelloides = Soldanella-like.

IRIS CRISTATA.

As I suspected, this exquisite little North American Iris needs to be a little better known to the Journal readers. My attempt to elicit a discussion upon its cultural needs, as first made in the opening article of this series of "Brief Notes on Alpine Flowers," has been a failure. As I remarked then, I have something to say on the subject, and, seeing that no one else has favoured us with their views, I must perforce lead off myself.

It is needless to disguise the fact that most of those who plant *Iris cristata* lose it at the first trial. This is a little discouraging, but is not surprising when we think of the small morsels which generally form these first plantings. Another obstacle in the way of early success is the common practice of covering with earth the rhizomes or rootstocks from which the true roots proceed. These should be on the surface of the soil, and not beneath it. I venture to assert that it is cheaper in the long run to pay a little more for a plant with several rootstocks, and that, if this is done and the Iris planted as recommended, there need be few losses.

Then as to the position, I am satisfied that one with a good exposure to the sun is the best which can be had. With such *I. cristata* will flower more freely and prove hardier than if even partly shaded. I grow it on a level terrace of a rockery, where it rambles about, seemingly delighted to place its rootstocks in contact with the stones. It is not, however, necessary to grow it on a rockery, as in many gardens, if once established, it will do well on the border. In the hardy plant nursery of Mr. Thomas Smith at Newry, Ireland, this Iris, planted as an edging to one of the borders grows with a luxuriance I have never seen surpassed. The edging is many yards long and one or more across, and when in full bloom must be of exquisite beauty. Another instance which has come under my observation is to be seen in the garden of a flower-loving friend of mine to whom I gave some rhizomes to replace a small plant he had lost in a border. For some months it made little headway, but at length began to grow vigorously. It is now a clump a few feet across. With regard to soil, generally speaking, I think it prefers a rather dryish soil in our climate.

An Italian firm recommends in its catalogue that *I. cristata* should have a "wet soil and moss cover," but of course the climate of the neighbourhood of Naples and that of the British Isles are quite different, and what may be needed in Italy may be injurious here. Although a dryish soil is, I think, preferable, it is not absolutely necessary, and once the initial difficulties of establishing this exquisite little flower are overcome, there will be little trouble with it afterwards. Once established, and when it has come into flower in May, everyone will be delighted

with its delightfully coloured lilac flowers, with the characteristic crest, whence the plant derives its specific name. It is only a few inches high, and the light green leaves harmonise perfectly with the delicate colouring of the flowers. I should recommend April, or, at least, early summer, planting so that it may become established before winter sets in.—ALPINUS.

(To be continued.)

ROYAL NATIONAL TULIP SOCIETY (SOUTHERN SECTION).—May 12TH AND 13TH.

THIS Society held its fourth annual exhibition at the Gardens of the Royal Botanic Society, in Regent's Park, London, on Tuesday and Wednesday, May 12th and 13th. Owing to the lateness of the season, and the frosts and hailstorms of April, the flowers shown were inferior, both in numbers and quality, to those shown last year. Several prominent exhibitors, among whom may be named the Rev. F. D. Horner, Messrs. Haynes, Thurstan, and Edom, being unable to be present. Two new exhibitors, Messrs. A. D. Hall and H. E. Greef, made creditable first appearances. Notwithstanding all drawbacks, there were some really fine flowers shown, Mr. C. W. Needham's twelve lacking nothing but another week's growth to equal any stand shown at the National for many years. Mr. Bentley's stand, which came second, was not nearly so good, his flamed bybloemens being weak. Mr. Chater's twelve contained some good flowers, but so young that they would not open. There was a better competition in class B, the first two sizes being very near together. Messrs. Hall and Greef had good stands in class C. There was an extra good competition in class D, for three feathered flowers. Mr. Bentley was easily first. In class E, for three flamed flowers, superior growth gave Mr. Hall supremacy over his northern rivals. In class K Mr. Bentley made a most meritorious exhibit. To stage ninety blooms in thirty varieties is no light task this season. Messrs. Barr worthily earned the gold medal of the Society with their comprehensive exhibit, and Messrs. Veitch showed some interesting and remarkable instances of what a Tulip could be when it forsakes the narrow road of rectitude marked out by the Tulip Society.

The best feathered flowers were Trip to Stockport, Mrs. Lea, Heroine, Masterpiece, Wm. Wilson, and Wm. Annibal; Sir J. Paxton, and Sam Barlow, Annie M'Gregor, Mabel, Sarah Headly, and Talisman were fine flames. Breeders were poor, being nearly all damaged by frost and hail.

Class A.—Twelve dissimilar rectified Tulips, two of each class.—First, Mr. C. W. Needham, Royton, near Manchester, with Sir J. Paxton and Sam Barlow (flamed bizarres), Masterpiece and Storer's Seedling (feathered bizarres), Talisman and Chancellor (flamed bybs.), Trip to Stockport and Adonis (feathered bybs.), Mabel and Annie M'Gregor (flamed roses). Mrs. Lea and Julia Farnese (feathered roses). Second, Mr. J. W. Bentley, Middleton, near Manchester, with Sam Barlow and Masterpiece (flamed bizarres), Magnum Bonum and Sir J. Paxton (feathered bizarres), Violet Sovereign and Chancellor (flamed bybs.), Chellaston Beauty and Mrs. Cooper (feathered bybs.), Rose Celestial and Mabel (flamed roses). Heroine and Comte de Vergennes (feathered roses). Third, Mr. A. Chater, Cambridge, with Sir J. Paxton and R. Headley (flamed bizarres), Sir J. Paxton and George Hayward (feathered bizarres), Duchess of Sutherland and Mrs. Jackson (flamed bybs.), Black Prince and Mrs. Jackson (feathered bybs.), Sarah Headly and Glory of Stapleford (feathered roses), Mabel and Sarah Headly (flamed roses).

Class B.—Six dissimilar rectified Tulips, one of each class.—First, Mr. Needham, with Sir J. Paxton and Hepworth's Seedling (bizarres), Talisman and Trip to Stockport (bybs.), Annie M'Gregor, and Mabel (roses). Second, Mr. Bentley, with Sam Barlow and Royal Sovereign (bizarres), Annie M'Gregor and Mabel (roses), Talisman and Elizabeth Pegg (bybs.). Third, Mr. Chater, with Dr. Hutcheon and Richard Headly (bizarres), Mrs. Jackson and Black Prince (bybs.), Mabel and Sarah Headly (roses).

Class C.—Six dissimilar rectified Tulips, for new growers.—First, Mr. A. D. Hall, Wye, Kent, with Sir J. Paxton and Wm. Annibal (bizarres), Adonis (feathered and flamed bybs.), Mabel and Madame St. Arnaud (roses). Second, Mr. H. E. Greef, Cambridge, with Sir J. Paxton, and Sophy Chater (bizarres), Mabel and Modesty (roses), Talisman and Bessie (bybs.).

Class D.—Three feathered Tulips.—First, Mr. Bentley, with Wm. Annibal, Adonis, and Mrs. Lea. Second, Mr. Needham, with Masterpiece, Adonis, and Modesty. Third, Mr. Hall, with Masterpiece, Mrs. Rathmeal, and Julia Farnese. Fourth, Mr. Chater, with Sir J. Paxton, John Linton, and S. Headley.

Class E.—Three flamed Tulips.—First, Mr. Hall, with Dr. Hardy, Annie M'Gregor, and King of the Universe. Second, Mr. Bentley, with Sir J. Paxton, Sarah Headly, and Duchess of Sutherland. Third, Mr. Needham, with Sir J. Paxton, Adonis, and Mabel. Fourth, Mr. Chater, with Sir J. Paxton, S. Headly, and Mrs. Jackson. Fifth, Mr. Greef, with Albert, Aglaia, and Duchess of Sutherland.

Class F.—Six dissimilar breeders.—First, Mr. Needham, with Storer's Seedling and R. Sales (bizarres), Annie M'Gregor and Mabel (roses), Hepworth's Seedling and Camp's Seedling (bybloemens). Second, Mr. Bentley, with Sir J. Paxton and Goldfinder (bizarres), Lloyd's Seedling and Mabel (roses), Adonis and Janette (bybloemens).

Class G.—Three dissimilar breeders.—First, Mr. Needham, with Sulphur, Adonis, and Annie M'Gregor. Second, Mr. Greef, with Excelsior, Friar Tuck, and Mabel. Third, Mr. Bentley, with Wm. Lea, Ashmole's 126, and Mabel. The premier breeder was Mr. Greef's Mabel.

Class H.—Pairs of Tulips, the Samuel Barlow Memorial prizes.—First, Mr. Hall, with Sir J. Paxton and Wm. Wilson. Second, Mr.

Bentley, with Sir Jos. Paxton and Masterpiece. Third, Mr. Needham, with Sir J. Paxton and Trip to Stockport. Fourth, Mr. Chater, with Duke of Sutherland and Rose No. 3. Fifth, Mr. Greef, with Lawrence Friend and Marshal Soult. The premier feather was awarded to Mr. Needham for Trip to Stockport, and Mr. Bentley had the premier flame with Sir Joseph Paxton.

Class K.—Ninety blooms of Tulips, in thirty named, dissimilar varieties, all classes to be represented. Prize: A silver Daffodil vase, given by Messrs. Barr & Son. Awarded to Mr. Bentley for a good exhibit, comprising Excelsior, Masterpiece, Sir J. Paxton (breeder and rectified), Goldfinder (breeder and rectified), Lord Stanley, Sulphur, Commander, Ajax, and Storer's 106 (bizarres), Lady Grosvenor, Aglaia, Queen of England, Rose Hill, Julia Farnese, Modesty, Clio, Annie McGregor (breeder and rectified), Mabel, Mrs. Lee, and Miss Edwards (roses), Bessie, Adonis, Duchess of Sutherland, Mrs. Ashmole, and Talisman (breeder and rectified), Nulli Secundus (bybloemens).

Class L.—Collection of Florist Tulips arranged for effect.—Silver medal, Mr. C. W. Needham.

Class M.—Display of English Tulips grouped for effect.—Prizes, the gold medal of the Tulip Society, and the silver medal of the Botanic Society, Messrs. Barr & Sons.

Class N.—Collection of Tulips, other than Florists'.—Silver medal, given by W. Robinson, Esq., Messrs. Jas. Veitch & Sons, Ltd.

Several interesting miscellaneous exhibits were represented, and amongst them Messrs. J. Laing & Sons, Forest Hill, staged a group of mixed plants comprised of Rose Crimson Rambler, Hydrangeas, Gloxinias, Calla Little Gem, Lilliums, Ericas, Cannas, and a few Orchids, together with foliage plants such as Crotons, Dracenas, Ferns, and Palms. Taste in arrangement added to the effectiveness of the group. Very pleasing was the exhibit sent by Mr. Charles Turner, Slough, consisting of Azaleas, fancy Pelargoniums, and Carnations. Amongst the latter were Malmaisons, Princess May, Sir Evelyn Wood, and The Churchwarden. A fine plant of Richardia Elliottiana was conspicuous, and Ferns and Palms were held in arrangement. Mr. Robert Sydenham, Birmingham, showed an Iris in a vase to illustrate his method of growing these bulbs in cocoa-nut fibre refuse and shingle without damage. Messrs. Kelway, Langport, showed a collection of Pæony flowers, which showed traces of having done previous duty in a similar capacity, as many of them were faded. A collection of Tulips came from Messrs. Jas. Veitch & Sons, Chelsea. Amongst others were noticed Magnet perfecta, lutea major, Velvet Gem, fulgens, Diamond, and Rose Crown. Ixias in variety were included in the collection. The silver medal presented by W. Robinson, Esq., was awarded to this exhibit.

The greater part of one side of the corridor was occupied by the varied and interesting exhibit of Messrs. Barr & Sons, Covent Garden. First came the Darwin section of Tulips, comprised of Glow, Erguste, White Queen, Loveliness, The Sultan, Zephyr, Flambeau, Hecla, and others. Parrot Tulips were staged in the shape of Large Yellow, Crimson Beauty, Coffee Cooler, and Admiral de Constantinople. Rectified Tulips were also shown in great variety, and in addition to the foregoing there were numerous vases, containing Irises, Pæonies, Scillas, and Narcissi, the whole making up the chief feature of the show, and worthily winning the silver medal of the Royal Botanic Society and the gold medal of the Royal National Tulip Society.

THE CONFERENCE.

The Conference, which had for its object the arousal of further interest in the cultivation of English Tulips, was held in the Museum in the afternoon of the opening day, under the chairmanship of Mr. J. Wright. In his introductory remarks Mr. Wright spoke of his own early interest in the Tulip, which had increased largely since his connection with that great lover of the flower—the late Dr. Hogg, who was the only man he had ever known who had given £90 for a single bulb. He was glad to be able to say that the days of fabulous prices were gone for ever, also that the Tulip was rapidly increasing in popularity, for not only was the flower used largely for the decoration of London drawing-rooms, but recently a Tulip Ball had been held in Surrey, when every room in the house was decorated with a different variety, supplied by Messrs. Barr & Son from the Ditton Nurseries. Though, concluded the Chairman, the Tulip was a native of the East, the flower in its most beautiful form was the result of the art of British florists, and those who grew and admired the English Tulip could appreciate to the fullest what has been and can be done by those who were and those who still are imbued with a love for the development of this stately flower. He then called on Mr. W. Bentley to read the first paper, remarking that it would be difficult to find a man better qualified to deal with the subject.

THE HISTORY OF THE TULIP.

Mr. J. W. Bentley, in the commencement of his paper, stated that so wide was the scope of his subject that it was impossible to treat it fully in so short an essay. The Tulip, he stated, was of Eastern origin, and had been grown for a long period by the Turks previous to its appearance in Vienna in the year 1559, and its subsequent advent into England in 1577. There were reasons for believing that the Turks had been raising new Tulips for a long time before their appearance into western Europe. Parkinson, writing in the year 1629, mentioned 149 varieties, and another writer in 1685 spoke of 300 varieties. Steadily the cultivation of the Tulip increased until in 1710 the vast number of names began to be a subject for ridicule. In France and Flanders, too, the Tulip held its popularity, and there is reason to believe that many of the so-called

Dutch sorts were originally French seedlings. Up to the year 1750 the Tulip held its sway, when its popularity waned somewhat in favour of American plants, which then found their way to our shores. During the early years of the present century the position of the Tulip was assured in the South of England, though it was not till 1840 that growers in the north began to perceptibly interest themselves, when such men as Storer, Ashmole, Jackson, and others took up the cultivation of the English Tulip with zest. For some time the interest in the flower was confined chiefly to the northern counties, though now it appears to be evenly distributed. Few growers, said Mr. Bentley, now raise seedlings, one bright exception, however, being the Rev. F. D. Horner.

Speaking on the properties of florists' Tulips, Mr. Bentley stated that the English section flowered about three weeks later than the Dutch, and with a knowledge of the capacity of the flower certain rules had been formed respecting good specimens. One was that the stems should be strong and sturdy, another that the flower should have six petals, and a third that when fully expanded the bloom should be shaped like half of a ball. The essayist then explained the constitution of the colouring which made up the three sections—rose, bybloemens, and bizarres. These classes are sub-divided into breeders, feathered, and flamed flowers. So far as he (Mr. Bentley) knew, no other flower breaks in the same way as the Tulip. The breeder is the seedling form whence we get the other sections. A breeder breaks, no one knows when or how, but therein lies the charm that appeals so much to Tulip lovers. They break into all forms, both bad and good, and it is important to get a good strain, as the same variety can and does exist in different forms.

It was formerly the custom not to name breeders until they had broken, but much confusion was the outcome of it, as for instance one grower might have one form under one name, and a second under another, though both were from the same breeder. Varieties excellent in the three forms are not numerous, though Sir Joseph Paxton is a striking instance of one. Sometimes the best coloured breeders break into bad flowers, and those that are dull in the first state break into most beautiful blooms. Mr. Bentley concluded by stating that the Tulip grower has to deal with an erratic and uncertain flower; sometimes he is disappointed, and other times more than pleased. He had not dealt lengthily with his subject, but if any further information were required he would refer those present to a series of articles he had written in the *Journal of Horticulture*, and he felt grateful to the late Dr. Hogg for the opportunity given, which resulted in their publication.

THE CULTIVATION OF THE TULIP.

The Chairman next introduced Mr. C. W. Needham, who at the commencement of his paper said that the Tulip was one of the easiest of plants to grow either in town or country. The bed should be well drained, and if the situation were at all wet the surface should be raised about 6 or 8 inches. Soil from the kitchen garden is suitable, but it should be porous rather than stiff. Turf may be used with advantage, but if so it ought to be stacked twelve months previously. He preferred to plant the bulbs 6 inches apart in rows, the beds being about 4 feet wide, and of any length. Some grew them 4½ inches apart, though he preferred the former as the orthodox distance. After planting the bulbs should be lightly covered, and later another addition should be made, leaving the bulb about 4 inches below the surface. No crude manure ought to be used, and though the same soil may be used for several years, a change is advantageous. If, however, the former method is adopted, it is a good plan when turning over to give a light application of salt or quicklime. Nitrate of soda, superphosphate, or kainit may be used moderately, but he preferred frequent change of soil. The object should be to keep the bulbs of average size. Gross feeding results in coarse flowers, and small sound bulbs invariably give the best blooms. Though the bulbs will grow and flower if left in the ground for the whole year, it is better to take them up and store them.

At the time of this operation the advantage of planting them 6 inches apart will be appreciated, as then there is little danger of injuring the bulbs on taking up. A cool dry place is the best for storing the bulbs, which on no account must be left on the ground, even for a short time, or the effects of the sun will be seen afterwards in the shrivelling of the outer skin. Tulip growers generally store their bulbs in boxes having a series of compartments arranged in order that the varieties may be not only kept distinct, but arranged in the beds. A Tulip book is also necessary, in order that the sorts may be classified, and notes made respecting them. The chief enemies of the Tulip grower are hail storms and frost, therefore if for exhibition some protection must be afforded. This, said Mr. Needham, can be provided by a covering of tiffany or an arrangement of garden lights placed over the beds. A critical time in the life of a Tulip flower is when they are first showing and the rain lodges in the axils of the leaves. If the moisture freezes it means death or disfigurement of the bloom; hence the advisability of giving protection. This is not a matter of so great importance to the ordinary amateur as to the enthusiastic exhibitor who wishes to get his flowers as faultless as possible. In conclusion Mr. Needham said that the cultivation of the florist's Tulip was simplicity itself, and there was nothing to daunt anyone who had the inclination from taking it up.

In the discussion that followed the paper Mr. Wright spoke of the fungus known as the Tulip disease, which to his knowledge had on several occasions played such havoc with the late Dr. Hogg's collection.

In reply Mr. Needham considered that the disease was a result rather than a cause, and after careful observation they had come to the conclusion that it was owing to the effects of hail and frost, which damaged the outer tissues of leaf and stem, and here the fungus made

its appearance. In supplementing this statement Mr. J. W. Bentley stated that the fungus attacked the injured parts, but, in his opinion, it afterwards spread to the healthy plants. In reply to another question respecting the theory of rectification in Tulips, he (Mr. Bentley) could give no idea of explanation. He had heard of several so-called theories, which, however, were too absurd to be entertained, and up to the present the matter remained a mystery.

Mr. Barr agreed with the essayist as to the cause of the disease, and said that it might also arise from the lack of air when the bulbs were resting, therefore a free current should be allowed to pass above and below the bulbs. He did not agree with Mr. Needham respecting the distance apart to plant the bulbs. He thought 3 or 4 inches ample, as they helped to protect each other; and in their nurseries he had noticed that during recent hailstorms those planted closely together were not damaged to such an extent as others dispersed at a distance of 6 inches. Referring to the proper time for lifting, he thought it should be done as soon as leaf and stem became limp, and could be easily bent in the hand without breaking. Mr. Chater was of the opinion that the disease was not a fungus at all, but the direct cause of hail or frost, as he had not noticed that it spread from one plant to the other.

Mr. Krelage (Holland) spoke of the disease as it affected Dutch plants. The cause is thought to be in the ground, as it is confined to locality. Scientific researches are, however, being made to ascertain the cause, and as a preliminary statement he might say that he thought the spread of the disease common in Holland was owing to the lack of some element in the soil, and where this was present no disease appeared.

Mr. R. Dean said that in the ordinary course a Tulip was a breeder first, and then rectified, and asked Mr. Needham whether he had ever seen a rectified Tulip go back to its original form of a breeder, to which he received a negative reply. Several other gentlemen took part in the discussion. The Chairman in thanking Mr. Needham for his highly instructive paper, said it appeared that the spread of the disease was the result of frost and hail. If, therefore, the plants can be protected and kept in a healthy state the fungus can be held in check. All therefore should be done to make the conditions as favourable as possible for the welfare of the plants, and as equally unfavourable for the spread of the disease.

HYBRIDISING TULIPS AND RAISING SEEDLINGS.

In the unavoidable absence of the Rev. F. D. Horner, the writer of the essay, it was read by Mr. Bentley. Writing of seeds and seedlings, Mr. Horner stated that the chief success lay in the selection of the best parentage; form mattered little, though the self-coloured section carried the best and largest seed pods. Explanations followed respecting the best points in the various classes of flowers, and which forms could be fertilised with the best results. Precautions must be taken after impregnation to prevent the inroads of bees; though there is no necessity to pin up the flower, a little cotton wool placed inside being quite sufficient. Unlike many other flowers, the Tulip does not close or die after hybridisation. When the petals have fallen the pistils should be removed, and after the swelling of the seed pods, which takes place in June and July. The seed pods may be taken off in August, when they commence splitting at the points.

The essayist explained the process of seed-forming, and in regard to sowing said that early in September was the best time, when the young plants will appear in February. The tiny seedlings, which resemble the earliest growth of the Onion, are perfectly hardy, and require no coddling. No further growth is made the first year, and probably seven or eight years will elapse before the bulbs bloom. They will, however, occasionally flower the fourth season. He, Mr. Horner, has sown the seed in the open ground and left the bulbs there till they have bloomed.

Speaking of the selection of new seedlings, Mr. Horner considered that the qualities can generally be determined as soon as the plant blooms. The Tulip in its breeder form was not of high moment, as bright colours were not necessary in obtaining good breaks. Often the best forms were got from dull breeders, and *vice versa*. In conclusion the essayist thought there was much remained to be done in the hybridisation of Tulips, particularly in the rose and hybloemen classes. Too much attention had been paid to marking to the neglect of form, and he considered the former was much ahead of the latter.

Mr. Bennett-Poë proposed a vote of thanks to the compilers of the essays, which was suitably acknowledged by Messrs. Needham and Bentley. The latter moved that a hearty vote of thanks be given to Mr. Wright for the able manner in which he had presided over the proceedings, and a brief reply brought the interesting Conference to a conclusion. Before the meeting dispersed it was suggested that steps should be taken for the publication of the essays.

ARNICA MONTANA.

SCORES of plants that are comparatively rarely seen, except in the collections of enthusiasts and in botanical gardens, are of very great beauty. Amongst these must be classed *Arnica montana*, which is depicted in the accompanying woodcut (fig. 89), for it is decidedly neglected by the majority of cultivators. On a rockery it has a pretty appearance, its bright orange-yellow flowers being freely produced, and at the present time it is very attractive. Of the ordinary shades of yellow we have abundant floral representatives, but a pure orange is not so frequently seen, and contrasts with many other colours very effectively.

ROYAL BOTANIC SOCIETY.

MAY 19TH.

THE show at the Royal Botanic Society's Gardens on Wednesday was held in the large marquee, a place admirably adapted to such exhibitions. The display, however, was not at all large; in fact, the tent looked somewhat deserted. The quality of the various exhibits ranged very high, Roses being particularly good. The competitive section was poorly represented as usual; indeed, without the miscellaneous exhibits the show would have been a failure.

Messrs. W. Paul & Son, Waltham Cross, arranged a handsome crescent-shaped group of Roses in pots, with boxes of cut blooms in the foreground. Crimson Rambler, La France, Enchantress, Madame Montet, Duke of Edinburgh, Aurora (new Hybrid Tea), Duke of Teck,

FIG. 89.—ARNICA MONTANA.

and Claire Jacquier were conspicuous. Mr. W. Rumsey, Joynings Nurseries, Waltham Cross, sent cut Roses and plants in pots. The quality of such varieties as Niphetos, Mrs. Rumsey, The Queen, and Souvenir d'un Ami was excellent. Mr. J. Odell, Goults Green, sent Canterbury Bells in pots.

Mr. C. Turner, Slough, sent a group of Azaleas and Pelargoniums, all of good quality and effectively arranged. Palms, Ferns, and Spiræas were utilised for diversity. Mr. R. Scott, gardener to C. Newington, Esq., The Holme, Regent's Park, staged a miscellaneous group of flowering and foliage plants. Amongst others were noted the yellow Calla, Clerodendron Balfouri, Cannas, Zonal Pelargoniums, Azaleas, Ferns, Palms, Dracænas, and Caladiums. Messrs. J. Waterer & Sons, Bagshot, sent a collection of named Rhododendrons in pots, comprising many varieties of great merit. Mr. J. R. Box, Croydon, staged Calceolarias in very good form.

The Tulips sent by Messrs. Barr & Sons, Covent Garden, made a bright display, the interest of the exhibit being added to by the use of Irises, Delphiniums, and Daffodils. There were Darwin Tulips, besides breeder and rectified florists' varieties. The colours, substance, and

form of the flowers were of great merit. Messrs. T. Rivers & Son, Sawbridgeworth, sent a group of Peaches and Nectarines in pots. The specimens shown were grown in the very best style, the wood and foliage being clean and healthy and the fruit richly coloured. Cardinal Nectarine was superb. Mr. W. Bull, Chelsea, sent a few new plants, and Mr. Kelf, gardener to Mrs. Abbot, Regent's Park, splendid Royal Sovereign Strawberries in pots, besides Peas and Lettuces.

Mr. W. Rumsey, the only exhibitor, secured the first prize for nine Roses in pots, while in the class for a group of greenhouse Azaleas equal first prizes were given to Messrs. Kemp and Wilson and Mr. W. Holmes, the latter showing the better-grown plants, and the former larger numbers. Messrs. Kemp and Wilson were again first for six Azaleas in pots. Gloxinias, Orchids, and Ferns were also shown, but in each case there was practically no competition.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. A. F. Barron, The Royal Gardeners' Orphan Fund, Chiswick, W.

THE YOUNG GARDENERS' DOMAIN.

FORCING FRENCH BEANS.

"W. W." (page 419) claims for the growing of French Beans in small pots to gather a week or two earlier. As we can gather Beans from our large pots in six weeks from sowing, I take it that "W. W." can gather them in a month, and that in the depth of winter. I know it is easy to produce good Beans in November from autumn sown plants, but dare not hope to reach or break "W. W.'s" record of time or quantity in winter or in spring. Also he claims for the potting-on system that it must be better on account of the fresh soil used. With good drainage and careful watering, I fail to see how the soil can get stagnant in the time. With regard to liquid manure we have tried both ways with plants side by side, and I have yet to learn that the crop is larger or heavier by the use of it.—STONE WARRILOW.

GERANIUMS FOR WINTER BLOOMING.

CORRECTLY speaking these are Zonal Pelargoniums, but the old incorrect name clings to the plants with a sort of loving tenacity. Having secured strong well rooted young plants we pot them in 60's, using light generous soil. After we have grown them for about a month in a temperature of 60° to 75° they are shifted into 32's, using a compost of sound loam two parts, leaf mould one part, bonemeal, wood ashes, and soot in equal proportions to form one part, also a dash of coarse sand. They are potted moderately firm. We give them similar treatment to the above, keeping the syringe going among them for six weeks, after which we gradually harden them outside. The blooms are kept picked until the last week in September. The feeding they get is soot and manure water, with about four applications of nitrate of soda. The treatment I have mentioned produces for us any amount of bloom, plenty of plants bearing six and seven fully developed trusses at a time. Out of the fifty varieties we grow I prefer these twelve:—Brilliant, F. Arago, Mrs. Johnson, Olivia, Omphale, Aphrodite, Lady Chesterfield, Constance, Mrs. Keeler, Madame Chrétien, Rev. F. Atkinson, and F. V. Raspail.—ELVASTON.

[If "Elvaston" desires to see more of his notes in print he must leave at least twice the amount of space between the lines for the purpose of revision. Some of his lines had to be eliminated.]

A FEW NOTES ON THE DAHLIA.

WHERE summer bedding is practised on a large scale the Dahlia is grown extensively and to great advantage. In some cases it occupies large beds, and forms the centre of others. It is also grown in mixed borders and in beds set apart for cutting purposes, being one of the most useful flowers for house and harvest festival decorations. Plants that were started in March in a moist and brisk bottom heat will now be making free growth, and should be gradually hardened for planting out at the end of the present month or the beginning of June.

The Dahlia is a gross feeder, and if fine flowers are required the soil in which the plants are to be grown must be made very rich. The ground should have been deeply trenched and thrown up roughly the previous autumn or winter. It is not necessary to manure the ground at that time, as at planting the sites can be marked out for the plants, which should be from 4 to 6 feet apart, two or three spadetuls of soil thrown out, and as much manure added, thoroughly mixing the manure with the soil. Planting can then be done, placing some fine soil about the roots, and pressing the whole firmly about them.

At the time of planting a strong stake must be provided for each plant, and to this the plant tied and made secure against harm from winds. The plants should then have a thorough watering. The principal work afterwards will consist in attending to watering, tying, and looking after insects. Earwigs are the most troublesome pests of the Dahlia, eating as they do the young foliage as well as the blooms. They can be

trapped by placing a small flower pot inverted, with a little moss in it, on the top of the stakes.

As the plants make growth it will be necessary to keep the young shoots securely tied to the stakes, and during hot weather the plants will be benefited by having the soil about them slightly loosened, and a mulching of rich manure placed over it. Disbudding should be attended to, and if fine blooms are required four to six shoots should be grown on each plant, according to the variety. Those producing large flowers may be allowed to carry the most shoots. I think the Cactus varieties are now the most popular, although the single Dahlia is extremely useful for decorative purposes.—YOUNG PRACTITIONER.

HANGING BASKETS.

WHAT cold, bare-looking places our conservatories and greenhouses would be without a few hanging baskets. They seem as it were to put the finishing touch to a well-arranged house, no matter whether it be occupied by foliage or flowering plants. In these days of copper wire and artistically made wooden baskets let us not forget that for anything to look really well it must be as natural as possible. Fancy wood and wire baskets are good for a change, but they are less natural than the old rustic baskets with pieces of cork projecting among the plants, improving the general appearance.

Plants should be selected suitable for the positions the baskets are to occupy. For a light stove we have the beautiful *Centropogon Lucyanus*, which, with its masses of bright rosy-coloured flowers, is a gem for winter, and the old stems are flowering now profusely. This may be alternated by baskets of *Nephrolepis exaltata*, with an edging of *Panicum variegatum*, or *Tradescantia zebrina*. *Asparagus deflexus* also looks well in the stove.

Among those which succeed under shady and cooler conditions are the *Platyceriums* (Stag's Horn Fern), *Pterises*, *Adiantums*, *Davallias*, and *Woodwardias*; while for companions of pendent habit to associate with them I may mention *Selaginella denticulata*, *Panicum variegatum*, *Pilea muscosa*, and *Tradescantias*.

Turning our attention to the conservatory and light flowering houses, we have plants almost without number suitable for baskets. Ivy-leaved *Pelargoniums*, *Fuchsias*, *Tropæolums*, of which "Coolgardie" is a deliciously scented variety with large yellow flowers; *Lachenalias*, which ought to be basketed in August, placing the bulbs all round the sides, top, and bottom of the basket as it is made up. Winter the baskets in a cool structure, giving little or no water, and place them in gentle heat in early spring. *Achimenes* require to be treated much the same as *Lachenalias*, except they may be basketed in February and placed in heat at once, removing them, together with the *Lachenalias*, to a cool house as soon as they are well on the move. *Lobelias*, *Musk*, *Campanula isophylla alba*, with the dark species *purpurea*, and a host of others make a grand display the greater part of the year. Thus we see by the few plants enumerated that we are not without material with which to furnish our rustic receptacles.

The preparation of these is as follows:—Procure some live moss, or, if difficulty is experienced in obtaining moss, turf that has been in stack for three months will answer the purpose; line the baskets with the same, place the centre plant in position, and add soil as the work of planting proceeds, finishing with a ring of small plants of the chosen creeping kinds. Water well in bright weather, which will be almost all the attention required, except perhaps a few pegs may be needed to keep the trailing plants within bounds until they cover the baskets, after which time they may be allowed to hang down naturally.

Touching the Editor's note on page 349, I beg to say that at the time of writing in the Midlands we have not yet finished playing football, though possibly, as he suggests, the "willow" will have an irresistible charm in the near future.—YOUNGSTER.

[We should be sorry to deprive, if we could, any "youngster" of healthy, enjoyable, reasonable recreation, but some Midlanders seem almost to go mad over football, and cricket cranks are not unknown. Not very long ago a young gardener, and we believe a good one, was so proud of his accomplishments in the field that amongst other testimonials that he presented in seeking a much-coveted situation was one that recounted his ability as a cricketer. This lost him the position he sought as head gardener and a salary of £100 a year, with et ceteras. We have seen the testimonial, also the young man, as well as the gentleman in question, who could not be induced to change his mind and give the young gardener a trial. Trouble, he said, had arisen through an abuse of privileges, and he would run no further risks.]

NATURE'S LARDER.

THE prolongation of life in the vegetable kingdom consists in its members during growth receiving a fair abundance of readily absorbable nutritive matter. The agri-horticultural brotherhood, aided by chemists, have unitedly, by observation in practice and laboratory experiment, massed many valuable principles for our guidance in vegetative culture.

By Mr. W. Dyke's process, recently described in this paper, we might classify soils—namely, weighing a quantity of a certain kind (perfectly dry) and burning it to find the loss of organic matter; or by shaking samples of soils in jars of water, to separate the clay from the sand. Thus we have sandy soil, 90 per cent. of sand; sandy loams, 10 to 40 per cent. of clay; loamy soils, 40 to 70 per cent. of clay; clay loams, 70 to 85 per cent. of clay; and so on. A marl is a soil with 5 per cent. or so of calcium carbonate (CaCO_3). Calcareous soils have over 20 per cent. of lime.

Mr. Dyke in his instructive chemistry lessons has explained how soils

are formed; how by rock decay, plus the et-ceteras, we are blessed with a food supply, whereby the herbage of the earth finds sustenance. A fertile soil should contain from 9 to 15 per cent. of humus—i.e., vegetable mould, and 85° or 90° of mineral matter. Thus soils are chiefly composed of humates, phosphates, silicates, carbonates, nitrates, and other combinations. Ammonia and carbonic acid gases permeate the whole, or ought to, if we are to have a productive agent. When an acid such as phosphoric acid combines with another (H_3PO_4) substance, its last letters, "ic," are changed to "ate"—phosphoric acid and potash = potassic phosphate.

A sandy loam is cultural desideratum, unfortunately not often met with. In cases of heavy clay lands artificial means must be applied to obtain from it the hoarded constituents. Drainage in such a case is of infinite value. All land on which water remains longer than two hours after rainfall requires our aid to free it from stagnation. Drains are placed 2 feet deep on very heavy land, and deeper according to texture. On medium soil drains might be 9 feet apart, never less than 4 feet deep, and having a fall of from 1 foot in 50 to 1 in 150. The main drain or outlet must always be determined before cutting operations commence. I have only had opportunity of seeing tile drains laid, although I believe that large flat stones placed triangularly or square when well firmed, and the soil beaten tightly over and under them, are suitable and efficient where stones are plentiful. The "run" of drains generally goes with the slope of the land.

I am not sufficiently well acquainted with the details of measuring, levelling, and tile laying to give all information. Suffice it to say that, having marked off the drain lines, and having all tools ready, set to work, and continue to work well and with accuracy, straight and clean; lay the tiles firm and close; see that sufficient fall is allowed; place over each tile a turf, and fill in the worst quality of soil over the turf. Do not scatter the surplus soil after filling in the drain, remember the sinkage. Thus briefly have we outlined a system of drainage, the good effect of which we shall inquire into.—A YOUNG SCOT.

(To be continued.)

CINERARIAS.

EVERY gardener is familiar with this attractive winter and spring-flowering plant. It is useful to the private gardener for house decoration, for a display of bloom in the greenhouse or conservatory, and also for cutting. It is useful to the market grower as a sale plant, for making into sprays and other purposes.

Cinerarias are easily raised from seeds, or offsets taken from the old plants; but the latter method is only practised in the case of named and double varieties. Seeds are sown at different periods, ranging from April to July, according to the time the plants are required to flower. Sow thinly in pans, comprising a mixture of sifted loam, leaf soil, and a small quantity of sand, previously watered. Cover the pans with a sheet of glass, and place in a cool position, never allowing the soil to get dry. Seedlings will soon appear, and when large enough to handle they can be pricked into pans, containing the same kind of compost as before. The next move required by the plants will be into large 60's, taking care to secure as much soil with the roots as possible.

After potting arrange the plants in a cool frame containing a layer of ashes or some other material to afford a moist base for the pots to stand on. The frame should be kept rather close for a short time, the plants shaded from the sun, and also frequently syringed. When the roots have filled the small pots the plants may be transferred to the size in which they are required to flower, 6 and 7-inch pots usually being employed. Suitable soil for potting this time is a mixture of fibry loam, broken into lumps about the size of a Walnut, leaf soil, silver sand, with a little dried cow manure added. The plants may be arranged in frames as before, and as soon as the roots take possession of the new soil air must be freely admitted.

During bright weather a shading of tiffany is helpful, and syringing twice or thrice a day beneficial. As soon as the flower heads appear weak liquid manure may be given, also an occasional top-dressing with artificial manure will be found beneficial to the plants.

If large flowers are required disbudding may be practised, removing one-third of the buds, taking care that these are the smaller. Disbudding is always required in the double varieties.

Cinerarias are liable to attacks of green fly and mildew. The former can be removed by fumigating with the XL fumigator, or with tobacco, and the latter by dusting the plants with flowers of sulphur, or by syringing them lightly over with a solution of Calvert's carbolic soft-soap at the strength of 2 ozs. of soap to a gallon of rain water.—ELVEDEN.

MAGNOLIA STELLATA.—This is the earliest of the hardy Magnolias to open its blossoms. As early as the middle of March the flowers began to open, and before the end of the month the plants were one mass of pure white blossoms. The flowers are star-shaped, and average from 3 to 4 inches across. They are produced with great freedom, plants 2 feet high by 1½ foot through often having from twenty to thirty fully expanded blossoms on them at one time. In England it attains a height of from 3 to 4 feet, and assumes rather a stunted habit of growth, possibly due to the freedom with which the flowers are produced. When planting a mixture of peat and loam should be given, and care taken not to injure the roots. For forcing this plant is admirable, the waxy star-shaped flowers making a striking contrast to many others which are used for a similar purpose. A bed of this charming Japanese shrub is to be seen outside the temperate House at Kew.—W. D.

HARDY FRUIT GARDEN.

Thinning and Regulating Young Growths.—When the dis-budding of fruit trees, especially those which require constant and regular attention in this respect in the early stages, has been neglected and the superfluous shoots have been allowed to extend too far before attempting their entire removal, gradual thinning with the knife must be resorted to. It is not nearly so easy to insure good results with Apricots, Peaches, Nectarines, and Morello Cherries when the thinning and regulation of the growths are not adopted early, so that those shoots finally retained may have the full benefit of light and air. On the other hand the reduction of the number of shoots ought not to be too severely carried out. It is best to retain more than are actually wanted for fruiting. This provides a good selection at the winter pruning, when the best can be nailed in and the remainder cut out.

Plums and Sweet Cherries.—The laying in of young shoots wherever wall space is available for them to be developed and perfected without crowding is a good method of insuring a fruitful condition of the trees. Similar shoots, however, laid in in the previous year may not show a decided tendency to form fruiting spurs all their length, but rather to produce young growths. Whether these side growths are few or many they will, if left to extend, more or less crowd the trees. All such had better be pinched at the third large leaf. This greatly assists in concentrating the vigour in the formation of artificial spur growths. The upper buds of these shortened shoots will almost certainly start into growth—lateral growth—which must be pinched back to the first leaf. Growths will again start from these. This is termed sub-lateral growth, and as often as made should be pinched to the first leaf throughout the season. Prune the whole back to the lower bud or buds near the main branch in winter. Artificial spurs are formed in this way. Short, stubby, natural spurs require no shortening.

Thinning Fruit.—Apricots, Peaches, and Nectarines should have the first thinning of the young fruits when the latter have attained to the size of horse Beans. Those most advanced in swelling are the best to retain, because they are properly fertilised. Remove the small, weak, and ill-placed fruits first. This thinning will suffice for a time, or until the fruits reach the size of Hazel Nuts, when they ought again to be looked over, removing the least promising. If the fruits have not set very thickly the earlier thinnings may be dispensed with. It will, however, be useless to retain fruits in unsuitable positions where they have not room to swell properly. In light cropped trees these only need removal. Early gatherings of Gooseberries may now be made. The berries are useful for tarts, and by some are preferred when rather small. These pickings suffice to thin the bushes.

Mulching Fruit Trees.—Trees and bushes promising to bear full crops of fruit may be assisted materially in perfecting the fruit if the soil over the roots is covered with a layer of short manure. Spread it about an inch thick as far as the roots extend, adding to it, if necessary, at intervals throughout the season. The beneficial effects of a mulch over the roots in a dry season are apparent in the moist condition of the soil. Short grass also affords material for mulching, though it does not contribute any support to the roots, or enrich the soil until thoroughly decomposed. Trees that are fruitless ought not to be freely mulched with rich manure if they are making strong growths, but if weakly a liberal dressing will prove most beneficial. Young trees recently planted must be lightly mulched, so that the rapid evaporation of moisture from the surface soil may be arrested. The roots of Raspberries and Currant bushes multiply abundantly near the surface when it is kept cool and moist with layers of good manure.

Strawberries produce strong flower trusses, which open and set freely when the plants are supported with a mulching of manure between the rows. It also obviously assists the fruit to swell up to a large size, and prolongs the season of fruiting.

Watering Strawberries.—In very dry weather Strawberries, even when mulched, will be benefited by applications of water to the roots during the time the plants are in flower and setting fruit. Liquid manure may also be given, though in a clear state, and avoid discolouring the fruit.

Watering Wall Trees.—The soil at the base of walls, in which the roots of fruit trees extend, is subject to considerable drying influences. The foundation of the wall allows moisture to drain away readily, while the large expanse of foliage abstracts a great amount of the water which the roots take in from the soil. This demand upon the soil moisture will continue through the season, increasing rather than diminishing; therefore, before the trees begin to feel the effects of dryness, apply a liberal soaking of water to the roots. Lack of moisture in the soil is frequently the cause of young fruits falling prematurely, and others failing to swell. Much of the moisture thus applied may be conserved by giving a dry mulch afterwards.

FRUIT FORCING.

Peaches and Nectarines.—*Early House.*—When the trees of Alexander, Waterloo, and Early Louise Peaches, with Cardinal and Early Rivers Nectarines are cleared of the fruit, the shoots on which the

fruit has been produced should, if not required for extension, be cut away to the shoots that are to produce fruit next year. This admits light and air, and the foliage is more under the influence of water for cleansing purposes. Syringe forcibly to cleanse the foliage of red spider, and if this and scale continue troublesome promptly apply an insecticide. The foliage must be kept clean and healthy, and over-maturity of the wood guarded against by ventilating to the fullest extent after the fruit is gathered. Keep the borders moist, and in mild showery weather remove the roof lights. Stop or remove gross laterals, but allow some growth, as too close suppression of the laterals has a tendency to hasten the ripening of the growths, and when this occurs the buds may swell through over-development when they should be going to rest. Trees of Hale's Early and Dr. Hogg are now ripening the fruit, closely followed by Stirling Castle, Dymond, and Royal George Peaches, while Lord Napier and Stanwick Elruge Nectarines are fast changing colour also. These are all first-class forcing varieties, and combine high colour with excellent quality. When the fruit is ripening it must not be syringed unless red spider appear, when a forcible syringing should be given on a fine morning. If water lodge on the fruit for any length of time the skin cracks and mould infests the flesh, imparting to it an unpleasant flavour. Supply sufficient water at the roots to maintain the foliage in health, but avoid an excess in the soil and atmosphere, as it has a tendency to induce splitting at the stone in certain varieties.

Trees Started in January.—When the trees are of the varieties first named in the preceding paragraph they will be ripening the crop, and must be treated as therein advised; but when of the midseason kinds of Peaches and Nectarines the fruit then will be swelling rapidly, and must have every encouragement. Above all things expose them to all the light possible, turning the leaves aside. This is apt to cause the fruit to ripen too fast on one side, but it may be prevented by placing a thin piece of paper over and just clear of the fruit in the hottest part of the day, so as to subdue the force of the sun. Maintain a circulation of air constantly by a gentle warmth in the hot-water pipes, keeping the temperature at 60° to 65° at night, and 70° to 75° by day artificially. Spare no effort to eradicate red spider before syringing ceases, as it should when the fruit commences to ripen, otherwise the pest will increase so rapidly as to prejudice next season's prospects by its ravages on the foliage. Thoroughly water inside borders, also outside ones if necessary, and supply a light mulching of lumpy manure, such as spent Mushroom bed material or partially decayed stable litter, keeping it moist by sprinkling when it becomes dry.

Succession Houses.—Allow trees time to stone, not hurrying them, or they may be so exhausted as to ripen the fruit prematurely if it be not cast in the process. Root action will be encouraged by a free retention of the laterals on weakly trees, and their removal on strong trees will somewhat check their activity; but these extensions and restrictions must not be excessive, as the fruit will be prejudicially affected. Avoid crowding the principal foliage, and keep insect pests in check by syringing the trees twice a day. Thin the fruits where too thickly placed, removing all surplus ones when stoned, and turn the others to the light, so that they may colour from the apex. Supply water or liquid manure to weakly trees, but do not feed vigorous ones, as that will only aid growth and hinder stoning. Admit air early and close in the afternoon with plenty of atmospheric moisture, so as to raise the temperature to 80° or 85° when it is desired to accelerate the fruit, and ventilate a little afterwards for the night, so that the temperature may fall to between 60° and 65°. Maintain these temperatures by artificial heat in the daytime; they will be ample until the stoning is completed.

Later Houses.—Overcrowding is a great evil. Train and tie in the young shoots that are to carry next year's crop, and allow them to extend as far as space permits. Stop or remove all gross shoots, and pinch side growths that are not wanted for next season's bearing or for furnishing the trees. Thin the fruits, leaving only a few more than are required for the crop, and apportion the fruits to the vigour of the trees. One fruit to each square foot of trellis is ample for Peaches of the large varieties. Nectarines may be left at 9 inches. Syringe the trees twice a day in fine weather, always sufficiently early in the afternoon to allow the foliage to become dry before night. If vigorous trees are dripping with moisture in the morning omit the afternoon syringing. Supply water when necessary, so as to moisten the soil down to the drainage. Open the sashes before the sun acts powerfully on the foliage, and increase the ventilation with the sun heat, closing early if it is desired to accelerate the ripening of the fruit, but if wanted to ripen late admit air freely day and night. Young trees in course of formation will need dishudding, leaving the shoots for forming main branches 15 to 18 inches apart, and the bearing wood along them at a similar distance, training extensions their full length, and pinching the side shoots not required to extend to two or three leaves so as to form spurs. Pinch the laterals at the first leaf, and subsequent growths to one joint as produced.

Vines.—*Houses of Ripe Grapes.*—Afford fire heat only to prevent the temperature falling below 60°, and admit a free circulation of air. Do not allow the borders to become very dry, but keep them moist, and mulch with rather short, dry litter, from which the manure has been removed and the material washed by rain. It will retain moisture a long time, and lessen the evaporation from the surface of the borders. A little moisture in the atmosphere is not injurious to the Grapes, and is highly beneficial to the foliage, which must be kept clean and healthy. Fumigation or vaporisation must be resorted to if thrips appear; for red spider there is no remedy so safe as the tedious process of carefully sponging the leaves with tepid water in which about 2 ozs. of softsoap per gallon has been dissolved. Heating the hot-water pipes and brushing them with a cream of sulphur and skim milk must be done

very carefully, as it turns white Grapes purple, and hardens the skins of all so as to render them liable to crack and to become spotted. Place a double thickness of herring nets over the roof lights where Black Hamburgs are hanging, in order to enable them to keep their colour.

Succession Houses.—Bright weather greatly improves Vine foliage when proper regard is paid to ventilation, and utilising sun heat saves fuel. With sun heat and plenty of moisture more real benefit is derived in a week than in a month of dull weather with fire heat. The Vines being in full growth the temperature may be allowed to rise to 90° or 95°, closing the house at 85°, employing fire heat only to maintain a temperature of 70° to 75° by day and to prevent it falling below 65° at night, though it may recede to 60° on cold nights. These remarks apply only to Vines in full growth, as those which have Grapes approaching ripening should have a circulation of air, and those well advanced in ripening being kept cooler and drier. Admit air early in the morning, as the sun's rays act powerfully on the condensed moisture formed during the night on the foliage, causing scorching.

Watering.—Although stated interval waterings answer where the known requirements from long experience have been acquired, there are variable circumstances which upset calculations. Thorough supplies are usually afforded at starting to insure the moistening of the border materials to the drainage when the Grapes attain to thinning size and when they have commenced ripening. Those are essential feeding rather than watering periods, and ought to be carefully attended to, either by surface dressings washed in with tepid water or applications of liquid manure. In moisture-holding soils Vines may take no harm with those only, but inside borders of limited area require more frequent supplies of water. There are more failures from insufficient than over-waterings, the borders being properly constructed and the drainage complete. Watering twice a week in the case of those with the roots restricted to borders of limited extent, and once a week for those which have a good run of border, is not too much from the time the Grapes swell after thinning until the Grapes are changing colour. There is, however, a great difference in the retentive power of soils. Some loams are naturally very loose, sandy, or gravelly, and they have the usual opening materials added, such as lime rubbish and charcoal, which makes them still more sieve-like; the consequence is the greater need of the watering pot. Strong soil will require water less frequently, but in no case must there be any lack of moisture at the roots throughout the swelling period.

Late Vines.—These will either have set the fruit or be in flower in most places, commonly the latter. Maintain a night temperature of 70°. Shaking the rods twice a day will be sufficient in most cases to distribute the pollen effectively, but in the case of shy setters do not fail to resort to artificial impregnation, going over the bunches carefully with a camel's-hair brush. All large-berried varieties that are good setters, such as Gros Colman and Gros Guillaume, should be thinned as soon as the berries are set, and with those that are liable to have very closely set berries it is a good plan to thin them before the flowers expand, as a practised eye can tell which flower buds by their vigour are likely to set, and the removal of the weaker strengthens them wonderfully. Whilst the Vines are in flower do not pinch the laterals, but when the blooms are fairly set remove the laterals at once so as to prevent overcrowding.

THE FLOWER GARDEN.

Campanulas.—Canterbury Bells, notably the calycanthema forms, are very effective border plants, and in masses are most showy, being at their best in June, but will flower for some time longer. They are perfectly hardy, very few plants being lost during the late winter, and if seedlings are raised during May or the early part of June these can be grown to their full size by next winter. Sown in pans, not too thickly, lightly covered with fine soil, placed in a hand-light or close frame, the seed germinates quickly, and if the plants are first pricked out in other pans or boxes they ought to be ready for the open borders in August. They require good room, and ought to be eventually disposed not less than 15 inches apart each way. Room being somewhat scarce, put them out 8 inches apart each way, and in the autumn either pot up or transplant elsewhere every other row, and half the plants in the reserved rows. They move readily, and flower grandly in pots during May.

Wallflowers.—It is of the greatest importance that these be raised early, plants obtained by sowing after the stress of other garden work is over usually being too small and weakly to flower well. Sow the seed at once, preferably in open borders well prepared and got into a free working condition. Open shallow drills 10 inches apart, water these if at all dry through a rose pot, sow the seed somewhat thinly, and cover with a little fine or sifted soil. Thin out the seedlings early where at all crowded, leaving them say about 3 inches apart, and later on transplant every other one to other borders or beds. In sowing keep each colour separate, masses of one colour being most effective, and always aim to raise abundance. The double German Wallflowers to be similarly treated. Should there be no plots of ground convenient, raise the requisite number of plants in boxes, and prick out early.

Brompton Stocks.—These, though less hardy than Wallflowers, are yet frequently very serviceable, strong plants flowering freely at this time of the year. They are not well adapted for the flower beds, not transplanting well, but they are quite at home in mixed borders and in separate beds, always provided they can be well established in their flowering quarters during the summer. The seed may be sown now or

during the early part of June, and the plants treated much as advised in the case of Wallflowers.

Antirrhinums and Pentstemons.—Seeing that these plants are among the most showy for borders, and not to be despised for the flower beds, more than ordinary pains ought to be taken with young plants that may have been raised from either cuttings or seeds. Unless they are strong at the present time and be got out early on fairly rich good ground, the flowering period will be late and the spikes weakly. They transplant well from boxes or beds of soil in which they may have been temporarily pricked out, and being hardier than the ordinary bedding plants should be placed out early. They are really very effective bedding plants, a dry season appearing to suit the Antirrhinums well.

Herbaceous Phloxes.—To have these at their best they must be well fed at their roots, and young plants in fresh soil will in any case surpass the older clumps. The latter, however, may be greatly improved by having the roots bared and a mulching of manure and a soaking of water given prior to returning the soil over the manure. They are always dry at the roots, no amount of rainfall soaking the ground immediately about them after the growing season commences. It is also advisable to freely thin out the young shoots, any kept or raised in frames to be at once planted out on good ground. Strong young tops taken off, placed singly in small pots, and stood in a close frame with little or no bottom heat, root quickly, and these, if duly planted out, or given a shift into larger pots, will develop sturdy spikes of flower.

Other Strong Herbaceous Plants.—If the flower stems are crowded, the display is short-lived; but if thinned the stems branch more freely and flower more continuously, the quality of the flowers also being superior. All pay well for receiving the same liberal treatment recommended for Phloxes, and the least that can be done is to well thin out the Japanese Anemones, Delphiniums, Helianthus, Heleniums, Asters, Hemerocallis, and Pyrethrum nigrinosum, some of the last named being also cut half down next month in order to have them dwarfer. A mulching of short manure, leaf soil, or spent tan would also greatly benefit the foregoing and all other moisture-loving border plants.

Bulbous Plants.—These, with few or no exceptions, are best left undisturbed, not being lifted till it is necessary for them to be divided and replanted. This applies with the greatest force to the Daffodils and Narcissi, choice or otherwise, while the various other spring-flowering bulbs also improve if only disturbed every three or four years. Where they must be lifted and stored away in boxes defer the operation if possible till after the foliage has ripened and died off, but if this period has to be anticipated, as in the case of bulbs in the flower beds, take them up carefully and replant, or lay them in where they will not dry too rapidly. Bulbs of Hyacinths, Tulips, and Narcissi are not of much or any service for the flower beds in the following season, but they would serve to brighten the mixed borders, and in time give a good supply of flowers. Much the same may be said of the bulbs flowered in pots. They are of no further service for pot culture, but they might well be bedded in closely together in any outside border and be permanently planted in the mixed borders and the fruit borders next autumn.

THE BEE-KEEPER.

FALLACY IN BEE-KEEPING.

How is it so many statements are constantly being made in the public press as to the enormous yields of honey that may be obtained if such and such a thing is done? Bee-keepers are advised to use hives containing frames of comb a few inches longer or deeper than the generally recognised size, and are assured that by such means a much larger surplus is obtained. A "Border Bee-keeper," page 399, has done well to turn on the searchlight and expose one of such statements.

LARGE HIVES.

During the past week I have had a practical illustration of bees in large hives. Last autumn a bee-keeper in a neighbouring county died. His family knew nothing about bees or the handling of them, so they were left to take their chance during the winter, and as no surplus was taken from them last season they were expected to be in a better condition than others in that district. They were, with one exception, all in well made frame hives, having from fourteen to twenty-four standard-sized frames in each, and as they had not been opened for nearly a year I was asked to examine them, which I did thoroughly.

All the combs had been left in the hives, and as there was plenty of natural stores I was anxious to see what condition they were in when compared with others in the neighbourhood of only half the size. The first hive examined had twenty-four frames of fully drawn out combs, and was originally intended, I believe, for a double hive, as there was an alighting board at each end, but one entrance was stopped up. Several of the back frames were quite clear of honey; but a couple of frames in the middle of the hive

were full of sealed stores, and would weigh quite 8 lbs. each. The honey was as clear and liquid and the cappings as white as is usually the case in July.

Judging from this I came to the conclusion that the bees did not cover all the combs last summer. Brood was formed in five frames, and the bees covered seven frames on the evening of a cool day. This was the best stock, although the others had nearly as many bees, and all had prolific queens. The floor board (which was a fixture) of one hive was covered with dead bees, and it was with difficulty the live bees were able to pass. The dead bees and debris were all cleared out, quite a shovelful, and there was then a respectable colony of bees left. The queen had filled several frames with brood, and this stock will doubtless be as good as the others when the honey flow comes.

But what led to the loss of so many bees? as never in my experience have I seen so many dead bees in a hive. The hive was perfectly dry, and there were ample stores. I am inclined to think a stray swarm had taken possession during last summer and had killed the inmates. The condition of the above, as a whole, was no better or worse than others in the district that had been fed with sugar last autumn and wintered on ten frames, clearly showing that it is not an advantage to winter bees in large hives. A straw skep finished the examination, and although there was a nest of mice on the top, the bees, being strong and nearly ready for swarming, had kept them outside. There will be but few swarms this month unless there is more genial weather.—AN ENGLISH BEE-KEEPER.

DEAD BEES.

I AM sending a portion of a comb from a hive in which all the bees have died, I believe from starvation, as there is no food whatever in the hive; but on looking at the comb I see a great number of very small insects, and something which looks like a chrysalis. I should be glad to know if they are very injurious to bees, whether it is infectious, also if the combs will be fit to use again. My other hives appear to be doing well.—W. D. CHICK.

[The bees doubtless died from starvation, as the comb is clean and free from disease, and may again be used for either breeding or storing purposes. Before doing so, however, it will be advisable to remove the dust and debris from the comb with a soft brush. Should there be any remaining in the cells a sharp tap or two on a table will have the desired effect. It will also cause the chrysalis to leave their quarters.]

These are not injurious to the bees, as a strong colony would at once remove them. They are usually found in hives that have remained empty for a considerable time, and increase more rapidly in a damp place than a dry one. I have often found small beetles and chrysalis, similar to those forwarded, in combs that have remained on the stand several months after the bees were dead. "W. D. C." may rest assured they are not infectious. The chrysalis of the wax moth, which in some apiaries are very destructive, is much larger, and usually attacks combs when not in use; but if the instructions given in previous notes are adhered to no harm will happen to them. It is interesting to know your other stocks are doing well.—AN ENGLISH BEE-KEEPER.]

DIVIDING STOCK.

I HAVE two frame hives, one of which is overcrowded. I am anxious to divide one, but do not know how to go about it. Is this the proper time to do it?—P. L. T.

[If only one extra stock is required remove three or four frames of brood in various stages of development and all the adhering bees from the hive now overcrowded with bees, put them in a new hive, and place an empty frame of fully drawn-out comb on the outside of brood nest, draw the division board close up, and cover up warm. If there are not sufficient bees to well cover the brood shake the bees off another frame from the stock hive, otherwise the brood may become chilled; remove the hive 3 feet from the original stand.]

The stock hive should be moved 3 feet in an opposite direction, and the empty space caused by the removal of the frames closed up by drawing the frames together, with the addition of two more frames of comb or foundation; other frames may be given as required. If you are not an adept at finding the old queen divide the frames and adhering bees equally into two hives. A few days afterwards examine them, and the one that is queenless will be found to have already started several queen cells; extra frames must then be given to the stock containing the queen, and all will be well.

A young queen will be hatched in about sixteen days; by that time there will be plenty of drones on the wing, and the young queen will become fertilised and laying in less than a month from the time the stocks were divided.—AN ENGLISH BEE-KEEPER.]

THE BEE-MASTER.—Mr. J. Hewitt of Sheffield has issued the first number of a cheap paper for apiarians. He has chosen a good title, and evidently intends to make the columns lively. A trenchant writer himself, it may be expected he will find others of a similar character, and, as was observed by a bee-keeper to whom we handed a copy, "we must look out for stings," but old bee-keepers are said to be proof against the appendages, and smile when the timorous shudder with fear. It will be well for persons interested in the subject to look out for the next number of the new venture in apicultural journalism from Sheffield.

TRADE CATALOGUE RECEIVED.

Kelway & Son, Langport.—Plants.

° All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, *Rose Hill Road, Wandsworth, London, S.W.* It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Grapes not Swelling (*No Name*).—Names and addresses of correspondents should be sent. It is not uncommon for vigorous young Vines to fail to set the berries freely. The samples sent shall be examined more carefully than there is time for before going to press. In the meantime perhaps the name of the sender may be forthcoming.

Decorative Pelargoniums (*H. K.*).—If you read what we say below on packing flowers you will find you used the worst material—dry cotton wool. The petals fell off the moment it was removed from them; whereas if soft green leaves had been used instead the flowers would have been firm and fresh. We can, however, see that there are many varieties in cultivation superior to your seedlings, attractive as they are for decorative purposes.

Vine Leaves Blistered (*J. D.*).—The very fine leaves are blistered by a sudden admission of cold air, which caused a chill, and being afterwards followed by more genial conditions the sap rushed to the affected part and caused an enlargement or growth of new cells to repair the injury. This results in a thickening of the tissues, and the rusted appearance on the under side of the leaves. Although this is better avoided, as it may by timely and judicious early ventilation, the Vines are not materially prejudiced, especially when they glow with health as yours do, being deep glossy green on the upper surface, of stout texture, and perfectly clean. You have no need to feel alarmed, only attend carefully to the ventilation, and avoid cold currents of air. This is difficult to attain during the cold weather that has lately prevailed, and especially in situations near the sea, as the sun comes out powerfully after a period of dull weather, heating the enclosed atmosphere in a very short time. As this means expansion of moisture there is excessive evaporation from the leaves when air is admitted, which gives rise to the blister on the under-side of the leaves through the contraction and subsequent enlargement of the tissues. Keeping the high temperature would be likely to aggravate the evil, but the cause is a chill, and that more likely to be given on account of the greater heat during dull or cold weather.

Brompton Stocks (*Kewhurst*).—You appear to have sown the seeds between two and three months too soon. It is not the first mistake of the kind by any means. We have known some plants thus raised to flower in the autumn; a few of those that did not produced magnificent spikes the following year, but the great majority succumbed to frost. Your object should be to grow the plants slowly in hard and rather poor soil in a thoroughly exposed position, and a sufficient distance apart that the sun and air can have free play amongst them. They will then assume a sturdy habit and develop woody stems, in the best condition for resisting frost. If they are grown in loose rich soil in a sheltered position, and also in the least crowded, the plants will be tall, succulent, and tender, to be almost certainly killed in the winter. Hard soil containing lime is the best for the plants in the summer, and even then the growth may be luxuriant towards the autumn, in which case it is a good plan to drive a spade down 4 or 5 inches from the plants and sever the roots, half round each plant at first, doing the other half a week or so afterwards if a further check seems necessary. We have seen the plants established in 5-inch pots, these plunged over their rims in the open ground in the summer, withdrawing them on the approach of frost, and wintering them in cold frames. The end of May or early in June is a good time for sowing seeds of Brompton Stocks in the open air. The plants get quite large enough for standing the winter and flowering in due time. Perhaps you had better sow a little more seed in view of the possible failure of your present plants.

Peach Trees Casting Their Leaves (*H. S.*).—The leaves are injured by the sun acting powerfully upon them whilst wet, the tissues in some parts being practically destroyed, and the points of the shoots in some cases blackened. The fumes given off would to a certain extent cause the leaves to fall, as frequently occurs after fumigation, the leaves of Peaches and Nectarines being very susceptible to injury when growing. The fruits are infested with mildew, which certainly has not been killed by the specific used on one of the Peaches before us, and on the others it has so sunk into the diseased parts as to destroy the tissues to a considerable depth. This, however, may be partly due to the sun acting on the fruit whilst covered with the solution. The growths are very sappy, long-jointed, and pushing laterals at every axil. This would render them more liable to injury; indeed, such growths suffer most from fumes, producing a sort of scorching, and any sudden or severe check causes the leaves to fall. What the trees wanted were more air, less moisture in the atmosphere, and steadier supplies of nourishment at the roots. Lifting would do them much good, saving them from the ill-health and sterility into which, if the shoot before us be a fair specimen, the trees are assuredly drifting. We give you this hint for thoughtful consideration. In the meanwhile ventilate early, leaving a chink for air at the top of the house constantly, enlarging this before the sun acts powerfully on the house, not to lower the temperature, but allow the atmosphere to heat evenly with the increased sun heat. It certainly was not advisable to use the specific in the morning, nor three days in succession. For mildew on Peaches we have found dusting them with flowers of sulphur effective, making sure that the affected parts are reached by rubbing the sulphur on them by means of the fingers. We advise this now, and though it will not restore the damaged parts, it will not cause so much injury as the specific has done, aided by the sun and improper administration.

Soil for Cucumbers Treated with Lime (*A. G. W.*).—The sample of soil contains quite sufficient lime to correct the excess of humus, and give a steady supply of nitrate of lime, which is what the plants really require, and that will come fast enough, as the nitrifying micro-organisms appear exceedingly active, the soil swarming with them. There are also both eelworms and the sclerotia of the smother fungus, *Sclerotinia sclerotiorum*, but as the lime acts on the organic matter they will have a poor chance, especially if you use Little's soluble phenyle, 1 gill (quarter pint) to 3 gallons of soft water, as it kills both the parasites and aids the growth of the Cucumbers, giving value for outlay as a manure. Another good dressing for both eelworms and smother fungus is basic slag, 10 parts or lbs., kainit 5 parts or lbs., bone meal 1 part or lb., sulphate of iron half part or lb. mixed, using 4 ozs. (or 8 ozs. if before planting, forking into the soil) per square yard, washing in moderately. This may be repeated at intervals of about three weeks, supplying nitrogen in liquid form, say nitrate of soda $\frac{1}{4}$ oz. to a gallon of water, taking care not to overdo this, but being guided by the vigour of the plants, it being better to under rather than overdo the nitrate applications. A first-rate Cucumber grower has a tank holding 36 gallons of water, and as this comes in cold into the house he puts into the tank a good handful (about $\frac{1}{4}$ lb.) of nitrate of soda, and lets the whole stand full of water until warmed to the same temperature of the house before watering the Cucumbers with it, or if wanted sooner supplies the requisite amount of hot water. The water only contains about $\frac{1}{8}$ oz. of nitrate of soda per gallon, and he says—his crops verifying the statement—that it is quite strong enough for general use, and the Cucumbers like it, judging by their quantity and colour. We ask that you will use discriminative judgment, not overdosing the plants by using all the things at once, but in moderation, and at varied intervals, for plants like changes of sound food, not surfeits.

Pests Infesting Melon House (*T. K. M.*).—The insects are the common woodlice, *Oniscus asellus*. They are voracious, and fond of most things of a tender nature grown in gardens, especially Mushrooms, seedling Cucumbers, Melons, Tomatoes, roots of Orchids, and more than a taste of luscious fruits. They are very fond of bran. A farmer noticing how they swarmed under empty bran bags thrown on the floor of an outhouse took the hint, and spread the bags on the floors of his Cucumber and Tomato houses at night, for he was a market gardener as well as farmer, and in the morning had some pails of boiling water ready, which one person used, whilst another folded up the bran bags, carried them off, and shook them out in front of the farmyard poultry before they were fed. This plan answered splendidly, the empty bran bags being placed on the floor each evening for a time, and removed early in the morning. Another plan, and very effective, is to procure some old dry half-rotten boards, cut them into convenient even lengths, and place one board on the top of the other near where the woodlice haunt. As the boards do not lie evenly there will be sufficient space for the woodlice to get between them, or if not, form a slight space by placing a small stone at one end, so as to form a cavity. If a little bran be sprinkled on the lower board the woodlice like it all the better. Examine the boards every morning, and if you like to carry them away and spread the contents before poultry there will soon be an end of them, otherwise sprinkle the pests with boiling water. Another good plan is to place a little food, such as boiled Potatoes, bran, or pollard on the ground, in the angle formed by it and the wall, covered loosely with hay, and in the morning pour boiling water thereon. We have known woodlice congregate in the angle of a Mushroom bed wall an inch thick, and one dose of boiling water destroy thousands, without material injury to the Mushroom beds. It answers equally well elsewhere, taking care to bait in places where the boiling water can be used effectively without injury to useful plants.

The Journal (R. R. P.).—We are obliged by your appreciative remark that "the Journal continues to be as instructive and interesting as ever." This is published as applying to our various contributors, and we think they are fairly entitled to this recognition. The Journal varies as gardens vary. These are brighter at one time than another, but the changes rather add to than detract from their general usefulness, and the enjoyment derivable in and from them. Since we know that our literary coadjutors are able, practical, and zealous, we see no reason why the present standard which satisfies so many should not be maintained. Our hope is that it will be improved. The particular subject in which you, as well as others, are interested will be treated upon in an early issue.

Weevil Eating Vine and Peach Leaves (One Perplexed).—This pest, commonly and properly called the black-grooved weevil (*Otiorhynchus sulcatus*), is very widely distributed in England, and appears to be greatly on the increase. Whence it came in your case we are unable to say; but as you saw two last year there were probably many more about, and they increase rapidly from eggs, which give rise to grubs or larvae that feed on the roots of a great variety of plants, the parents preferring cultivated to wild plants. This may account for your receiving a visit from the weevils. The means you employ is one of the best for destroying them, and if persisted in will have satisfactory results, as by killing the weevils their continuing to do damage is prevented, as well as correspondingly hindering recurrence by making increase impossible. You ask, "Do they fly?" If you will look at one with a pocket lens the wing cases will be seen joined, hence flying is out of the question. Crawling, therefore, is their only means of getting about, and they are active enough when in search of food, travelling a considerable distance sometimes nightly, as on Vines and Peach trees. We have traced attacks from a distance of several hundred yards from one spot in one year, the female traversing the space from wild plants to deposit eggs in the soil at the base of Cyclamen corms. The practice you pursue will, if continued long enough, effect a clearance.

Muscat of Alexandria Vine Leaves Discoloured (J. H. S.)—The leaves have every appearance of being infested by *Plasmopora viticola* fungus or downy mildew, but there was neither the mould outside nor the mycelial hyphae of the fungus in the tissues. Indeed, we did not find any vegetable or animal micro-organism in connection with the diseased spots on the leaves. The yellow stains are purely of a chemical nature, such as usually arise in this variety of Grape Vine from an excess of chlorine, which is commonly administered in cheap forms of fertilisers and altogether unsuitable for Vines. This may be corrected by a free use of water as regards the soil, and the plant by supplying nitrogenous or ammoniacal manures, such as nitrate of potash or soda, and sulphate of ammonia. But a good all-round manure is best, say dissolved raw bones, five parts or lbs.; nitrate of potash, three parts or lbs.; sulphate of magnesia, one part or lb.; and air-slaked chalk lime and soot in equal parts by measure, two parts or lbs. mixed, using 4 ozs. per square yard, and washing in moderately. This will give colour and substantial benefit, but it will not restore the scorched and dead tissues to life. There has been some of this certainly caused by allowing the heated air to collect at the upper part of the house, and then air has been admitted, causing a chill or excessive evaporation, which amounts to the same thing. It is a great pity, as the foliage is not bad for Muscat of Alexandria at this time of year, and the more regrettable as it might have been prevented by timely attention to the ventilation. Muscat of Alexandria likes a generous dietary of humus, such as that had from native guano, blood and bone manure, so as to afford a steady supply of nitrogenous nourishment.

Points of Grape Vines Blackened (Vines).—The blackened or browned condition of the tips of the shoots and leaves is caused by the grey mould fungus of the Vine, a well known pest—*Sclerotinia Fuckeliana*. This, however, is the final stage of the fungus, which springs from sclerotia, or small black elongated tubercles, formed on or in the diseased tissues, and there rest during the winter. The form now on the Vine shoots is the conidial or summer condition of the fungus, and known as *Botrytis cinerea*, commonly called the Vine mould. The fungus is partly external, but yours is deeper seated than generally occurs. The disease usually appears on vigorous Vines, and especially those with downy leaves, such as Black Alicante and Gros Colman, its increase being accelerated by a moist and close atmosphere. The best safeguard, therefore, is a freely ventilated atmosphere, and not too much nutrition, such as commonly results from borders of rich materials. We, therefore, advise more air, and only sufficient water at the roots to keep the Vines healthy. The parts affected should be cut away and burned, otherwise sclerotia or black tubercles (externally black lumps of spawn) are formed on or in the tissues, and resting during the winter give rise to the disease in the spring. To arrest the disease you may spray the Vines with a solution of Cordy's red fluid, using a tablespoonful to a quart of water, or a wineglassful (2 fluid ozs.) to 1 gallon. The water must be soft and clear. It suffices to merely cover the growths with the finest possible film of the solution after the sun has left the house, repeating at intervals of about ten days. In the winter dress the rods with a solution of sulphate of iron, 1 lb. to 1½ gallon of water, applying with a brush. This will destroy the spores of the fungus in the crevices of the bark, and not injure the Vines when they are quite dormant. If the disease appears another season when the buds are expanding, at once spray with the Cordy's fluid solution. At the strength named it is usually safe on developed foliage, but it may have a slightly prejudicial effect on very tender and woolly growths, though we have not noticed any, yet it is as well to be careful, and try half strength first, or even a wineglassful of the red fluid to 3 gallons

of clear soft water. We mention this, as Vines differ greatly in susceptibility to injury, and it is easy to try the effect on a small scale before applying the solution on a large one.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Xchurck*)—2, *Philadelphus coronarius*; 3, probably *Phalaris arundinaria*. The *Rhododendrons* are probably seedlings, possibly of *amabile*. (*W. D.*)—1, *Prunus Padus*; 2, *Kerria japonica flore-pleno*; 3, *Adiantum assimile*. (*G. H. J.*)—1, *Doronicum plantagineum Harpur Crève*; 2, *Aubrietia Leichtlini*; 3, *Silene pendula*; 4, *Omphalodes verna*. (*E. S. Y.*)—1, *Leschanaultia biloba major*; 2, *Alyssum saxatile compactum*; 3, *Berberis dulcis*. (*W. C.*)—Specimen dry, a *Spiraea*, possibly *Thunbergi*. (*Wilts*)—1, *Saxifraga granulata flore-pleno*; 2, *Veronica chamædrys*; 3, name next week; 4, *Nemophila maculata*; 5, *Papaver alpinum*; 6, *Lychnis dioica flore-pleno*.

TURNIP CULTIVATION.

HOWEVER opinions may differ as to the value, or, rather, we should say the importance, of the Turnip crop to the average farmer, there can be no disputing the necessity for growing it well

if it is grown at all. And in this connection we may observe that it is a crop which lends itself to a forcing system of cultivation; it is rather an expensive crop up to a certain point, and by the aid of well-balanced manures prodigious crops may be grown with a fair amount of certainty. This applies more particularly to the Swedish variety, common Turnips when overgrown often being of very little value as food.

In the first place, what is the best time for sowing Swede Turnips? The time varies very much in different climates, but a good test is the temperature of the surface soil; when, on a sunny day, the hand can be held near the surface and feel a distinct warmth from that surface, Swedes may be safely entrusted to it. We all like to have a few early Swedes for use in the yards before Christmas, and the earliest sown are generally the heaviest crop; but we must not forget that the Turnip is a plant which cannot bear severe checks, so it is advisable to be guided by temperature rather than the almanack. A few acres may be sown experimentally in May, but, generally speaking, from June 1st to June 20th is the time for drilling Swedes.

As the Swede loves warmth we find it does not do well at high altitudes or on badly drained land, neither can it be grown on very poor hungry sand. On the former the Scotch and yellow hybrids are grown in place of Swedes, and on poor sand nothing is better than the Green Globe or Lincolnshire Red.

The most important thing of all is the texture of the soil; the Turnip produces exceedingly small seeds, so small that twenty-three are taken to make a grain, and upwards of 160,000 to the pound. Now it is obvious that the small rootlets put forth by so small a seed must have equally fine grains of soil amongst which to seek and find the food for the plant, and it would be only courting failure to sow such seed amongst earth which consisted of clods of different sizes, but none of them smaller than peas. A fine mould is an absolute necessity, and is the first thing the farmer aims at. Turnips invariably do well if a cloud of dust follows the drill, and the heat affects both horse and man.

Whether it is best to drill on ridges or on the flat is best left to the custom of the locality. On good easy working land we prefer ridging, for if manure is used it can be placed more directly beneath the plant. On strong soils, if there is a fine mould on the surface, it might be unwise to ridge, because the under soil might turn up very rough, and with a fine surface it were best to let well alone. Taking a look round different districts it will be found that ridging prevails on the best Turnip soils, that is where good tilth is the rule, and flat drilling is the custom on stronger and colder lands where a good mould is uncertain of attainment and the Turnip crop a precarious one.

Whether ridged or drilled we would not have the rows less than 26 inches apart for Swedes, and we would sow 3 lbs. of seed per acre. This is twice as much as some farmers sow, and no doubt many would say that it is a waste of seed, but we see others who sow less occasionally with only half a plant, and in constant anxiety if the Turnip fly be on the warpath; and there are not many seasons when he does not succeed in doing some damage.

The number of plants required for a crop, taking the rows at 26 inches and the plants at 10 inches apart, would be about 25,000 per acre. This number represents but a sixth of a pound of seed, so that by drilling 3 lbs. per acre we are apparently wasting seventeen parts out of every eighteen; but in order to get a regular plant, if the seed were sown at regular intervals of 1 inch, and then struck out so as to leave every tenth plant, $1\frac{1}{2}$ lb. per acre would be sacrificed; and if we allow another $1\frac{1}{2}$ lb. for deficiencies of growth and insect enemies, we do not think the allowance will be found too great. There is another point about having a fairly thick plant in the early stages—they seem to keep each other warm and grow faster; the chief drawback is that they must be singled as soon as ready, to prevent damage from overcrowding.

If well decayed farmyard manure be available this, at the rate of twelve loads per acre, with 5 cwt. of superphosphate (26 per cent.

soluble) per acre, should grow a satisfactory crop of Swedes. On heavy soils the manure should have been ploughed in during the winter, and the phosphate can now be drilled with the side. A combined manure and seed drill is used for this purpose.

As before observed, where the land is suitable for ridging the manure can be put on between the ridges and the phosphate sown broadcast at the same time; they are then split in together, and the seed drilled at once. It is very necessary to drill the same day, as a heavy rain coming in the night might make the ridges very sad, and too stale to drill well.

If farmyard manure is not available good Swedes can be grown with artificials. We have succeeded well with the following mixture:—100 lbs. nitrate of soda, 300 lbs. superphosphate, and 200 lbs. steamed bonemeal per acre. The two best varieties of Swedish Turnip to grow are Monarch for lighter soils and storing, Golden Melon for heavy soils.

WORK ON THE HOME FARM.

Another dry cold week, without absolute frost; but some of the nights have been very cold, with a temperature little, if anything, above freezing point. The last month has been splendid for twitching, and the fallows are practically clean, and ready for Turnips all round, so our horses should not have a hard summer, and we can have little anxiety as to the successful completion of work, until harvest at any rate.

Spring corn looks surprisingly well; it probably never looked better in mid-May, and given a showery June we should have some fine crops. Wheats have again fallen off, and unless a great improvement takes place during the next month they will be below the average. They appear to need rain, rather unusual for Wheats at this period.

The cold which has checked vegetation has helped off the old stocks of Potatoes. Trade has been quite brisk lately, and though the price has not risen much we have been glad to realise them at the figures now prevailing.

Thousand-headed Kale has come up well, and now is in second leaf. Some people advocate leaving it very thick, but we shall single ours just as we do the Swedes. The plants do not come to ripeness quite so early, but they produce much more food.

Pastures have fallen off, and want a nice rain (it is falling as we write, and hope it may continue). We find it a good plan to arrange for one field always to be clear of stock; for instance, we have three fields of grazing seeds, we divide our sheep into two lots, not three, so that we always have one field clear of mouths, and both freshening and growing sweeter. Sheep love a change of pasture. With the pastures rather bare a little oil cake will well repay the outlay; the sheep will more than repay the cost, and 30s. per ton is not too high a value to put on the gain to the land in fertility for each ton of cake used.

It is not too easy a matter to breed good horses. We may, therefore, complain of hard lines when a mare drops twin foals (dead) for the second year in succession, and another mare so far follows her example as to do the same thing for the first time. Twin lambs are a blessing; twin calves may be, but twin foals are an unmitigated nuisance when alive, and of no use dead.

REMARKS.

9th.—Sunny almost throughout, but cloudy at times in afternoon.
10th.—Brilliant early; frequently cloudy after 9 A.M., and spots of rain at 6 P.M.
11th.—Bright early; generally cloudy in afternoon; thunder at 5 P.M., and spots of rain in evening.
12th.—Generally cloudy with occasional sunshine.
13th.—Overcast early; alternate sunshine and cloud during day.
14th.—Fair all day, with a good deal of faint sunshine in morning.
15th.—Bright sun till 11 A.M., mild and pleasant after, with occasional sunshine; clear night.
A rainless and cold week—the 11th to 13th especially so—thus confirming the repute of these days in France as those of the "icy saints."—G. J. SYMONS.

JAMES CYPHER, Exotic Nurseries, CHELTENHAM.

FERNS A SPECIALITY.

We have an immense stock of all kinds of Ferns, Stove, Green-house, Filmy, Hardy Exotic, and British, including many very beautiful varieties, rarely seen but which ought to be more generally grown. Catalogue free on application.

W. & J. BIRKENHEAD, F.R.H.S., FERN NURSERIES, SALE, near MANCHESTER.

BEGONIAS.

Double and Single, Gold Medal Collection, for Conservatory and Exhibition, the largest and best in the trade. See Catalogue. BEGONIAS FOR BEDDING, superb quality, Double, 6s. and 9s. per dozen; Single, to colour, 5s. per dozen, 35s. per 100; 10 colours mixed, 4s. and 28s.; fine mixed, 3s. and 2/6.

B. R. DAVIS, YEOVIL NURSERIES, YEOVIL, SOMERSET.

150 ACRES Of Trees & Shrubs.

In the finest possible condition for the Villa, the Mansion, the Plantation, or the Game Cover. All in vigorous, healthy condition, not stunted, starved, or closely grown and drawn. Carefully and frequently moved, and the roots consequently are a mass of fibre, ensuring safe removal when sold.

NEW CATALOGUE, with descriptions of above, and of many Rare and New Plants. Post Free from

CLIBRAN'S Nursery, ALTRINCHAM

Also at Manchester, Bangor, and Llandudno Junction.

Journal of Horticulture.

THURSDAY, MAY 27, 1897.

THE TEMPLE SHOW.

THOUGH it does not seem very long since the Benchers of the Inner Temple first placed their charming gardens at the disposal of the Royal Horticultural Society for the purpose of holding a summer show, it is actually ten years. To-day (Wednesday) the tenth Exhibition opened, and as a whole the display is certainly equal to any of its predecessors, beautiful as these have been. In some respects the feast of flowers is better than ever, while the number of exhibitors has materially increased.

Statistics are not, generally speaking, particularly interesting, but the figures relating to the Show of 1888 and that of 1897 are worthy of a little study, for to an extent they convey an idea as to the growth of the Royal Horticultural Society during the last decade. Referring to our report of the initial Exhibition, it is found that there were requisitioned two tents, of which one measured 200 feet by 30 feet and the other 160 feet by 60 feet, and consequently covering an area of nearly 16,000 square feet.

Now look for a moment at the magnitude of the exhibition of to-day, when practically 26,000 square are canopied by the five marquees, the respective dimensions of which are 150 feet by 60 feet; 120 feet by 40 feet; 170 feet by 28 feet; 150 feet by 28 feet, and 110 feet by 28 feet, the three latter running along the broad walk which is parallel with the Thames Embankment. Of course, much of this space is taken up by the paths, but there are, to be precise, 11,800 square feet occupied by exhibits.

This seems enormous, but it is by no means too much; and if everyone had been allotted the space for which they asked a further 10,800 square feet would have been necessary. In other words, almost double the amount of ground could have been covered than is now actually the case. As an example of how some firms have been reduced mention may be made of one who asked for 1600 square feet and secured 250, while another wanting 300 had 75.

At first glance such wholesale reduction may appear rather hard; but the Society can only have one object—the most meritorious and diversified display. It is obvious that if each exhibitor were allowed all the space he asked for

there would be, with some at least, a difficulty in filling it without enormous repetition. Looking at flower shows from an educational point of view, the excessive duplication of plants or flowers is the reverse of appropriate, as the highest object is lost; and besides, the public soon tire of such masses as may be seen in the market.

Comparing last season's exhibition with this we see a few changes for the better in ideas, though in the majority of cases there is no deviation. Nor under the circumstances now existing can there be, for narrow tables are not ideal places for original arrangements. One feature we are very glad to see, and that is the return, after a brief secession, of Baron Schröder's unrivalled Orchids, which are a superb spectacle in themselves. From the largest tent let us turn for a moment to the smallest, where Messrs. Carter & Co., who have in a unique and charming manner erected a floral trophy in honour of the Queen's Diamond Jubilee, and in so doing have provided perhaps the most novel exhibit in the show.

From generalities we may now come to the tents, and what they contain, ere giving specific references to the plants, flowers, fruits, and vegetables. As is customary, the largest tent comprises the most effective display by reason of its height and width. Here are to be seen superb Roses in pots, artistically displayed; fragrant Malmaison Carnations; stately drooping Palms; delicately hued Caladiums; handsome Clematises; Peaches and Nectarines in pots bearing their luscious burdens, besides Orchids, rich in colour, diversified in form, and priceless value. It is a floral paradise, where quality is supreme, and quantity is ample.

As one passes into tent No. 4 one is met with richly coloured Begonias, plants new and rare, blue Leschenaultias, ducal Carnations, beautiful Calceolarias, brilliant Cannas, as well as Orchids, and the perfume of Roses. From one end to the other, on centre and on side tables, there is much that will interest and enforce the admiration of every visitor.

A breath of freshness comes with the rockwork in the third marquee over the broad walk; then there are hardy flowers of almost innumerable kinds, more Roses and Carnations, graceful Ferns of many forms, a gigantic and splendid display of Reading Gloxinias, which so clearly show what may be done with care and judgment in methods of culture.

Delicacy of colouration is the predominating feature of the Gloxinias from Chelsea, while the Streptocarpuses from the same source exhibit such remarkable improvements as would not have been dreamt of ten years ago. Putting tents Nos. 1 and 2 together we find beauty and utility combined to a degree that is seldom seen. The flowers are beautiful, the fruits and vegetables are magnificent. There are Peas and Beans in pots and boxes clothed with well-developed pods; Tomatoes literally roped with bright fruits; Peaches, Nectarines, Grapes, Figs, Apples, and Pears, as well as others, in the best possible condition, which reflect the very highest credit on their respective growers.

For the benefit of many readers who may not be familiar with the Temple Show we give (on the opposite page) from the Society's schedule a ground plan of the Inner Temple Gardens as they are to-day. From this visitors may know in which direction to go for any particular exhibit they wish to see. Below will be found a report of the major portion of the exhibits that are shown, and it need only be said here that in the disposal of the exhibits in the several groups, and in general high quality, the show exceeds all its predecessors.

ORCHIDS.

As was hinted in the introduction to the report, the Orchids make a bright, interesting, and rich display. The central table of the large marquee is entirely devoted to these plants, as well as a considerable portion on the middle staging in tent No. 5. When it is said that Sir Trevor Lawrence, Bart., Baron Schröder, Messrs. F. Sander & Co., W. Lewis & Co., and J. Cypher, with Major Joicey, Earl Percy, W. S. Ellis, Esq., and others, are represented, it will be known that there is much that is honestly worth the seeing. It is a matter for regret that Messrs. J. Veitch & Sons, Ltd., and R. J. Measures, Esq., do not exhibit on this important occasion, for they always stage plants that merit attention, either by reason of their rarity or their splendid culture. Perhaps in coming years they may be induced to contribute to, and so enhance, the beauty of the Show.

The town of St. Albans has during recent years become celebrated for its Orchids, owing to the prominence of Messrs. F. Sander & Co. in the Orchid world. Their exhibit is always of very great merit, and never more so than on the occasion now particularly under notice.

They are showing in quantity, while quality is by no means absent. It is impossible for us to name all those on the stand that deserve recognition, so we content ourselves with calling attention to those only that are particularly conspicuous, and amongst them may be mentioned *Dendrobium Dearei*, *infundibulum*, *Dalhousianum*, *Sobralia Veitchii*, *Odontoglossum crispum* and *polyanthum*, *Cattleyas Mendeli*, *Mossiae*, and *Skinneri*, *Calanthe Laucheana*, *Laelio-Cattleya The Queen*, *L. C. D. S. Brown*, *Laelia purpurata*, and others of the highest quality.

Though the exhibit staged by Mr. W. Buckill, gardener to Malcolm S. Cooke, Esq., Kingston Hill, is considerably smaller than the one just named it is very creditable, for the plants are clean, healthy, and as a rule well flowered. We might call especial attention to *Laelia purpurata*, *Cymbidium Lowianum*, *Cattleya Mossiae*, *Maxillaria Sanderiana*, *Cattleya Mendeli*, *Masdevallia Harryana*, *Dendrobium thysiflorum*, *Cypripedium villosum*, *C. bellatulum*, *C. Chamberlainianum*, *Cattleya Lawrenceana*, and *Oncidium macranthum* as being of quite average merit.

It is essential in an event of such importance as this that the south-western counties should be represented, and Mr. J. Cypher of Cheltenham worthily occupies the position. There is either something in the air of the Gloucestershire town or in the system of procedure in their culture that places a stamp of excellence on Mr. Cypher's Orchids which it is very pleasing to see. He does not come to London every day, but when he does it is with something really good. Very beautiful are *Laelia purpurata Meteor*, *L. p. Distinction*, *L. p. Russelliana*, *Thunia alba*, *Cattleya citrina*, *C. Mossiae gigantea*, *C. Mendeli superba*, *C. Mossiae splendens*, *Dendrobium infundibulum*, *D. Parishii*, *D. nobile majus*, *Odontoglossum crispum* in splendid variety, *O. Pescatorei virginalis*, light and dark coloured *Miltonia vexillaria*, *Tricopilia crispa superba*, as well as *Cypripediums*, *Masdevallias*, and others.

Last year hundreds of visitors were much disappointed when they discovered that Baron Schröder, The Dell, Egham, was not exhibiting, and many were the expressions of regret. This year the scene is changed, for the Baron is very strongly in evidence. Mr. H. Ballantine, the gardener, is a master in the art of Orchid cultivation, as everyone knows who has seen the plants at home. Look now at the splendid growth, the handsome flowers of the purest hues, and you will see Orchids as they should be grown. The staging, too, is very effective, for it is done so that the superb spikes of the matchless *Odontoglossums* may be seen with ease, while there is no suspicion of the crowding that is occasionally apparent in other portions of the exhibition. Singularly charming are *Odontoglossums elegans superbum*, *crispum mirabile*, *Halli leucoglossum*, *Miltonia vexillaria*, *Vanda teres*, *Odontoglossum crispum Sanderianum*, *O. lateo-purpureum Vuylstekeanum*, *Laelia purpurata*, *Thunia Veitchiana*, *Cattleya Mendeli*, *C. Mossiae*, *Dendrobium Bensoniae*, *Cypripedium bellatulum*, *C. George Keltie*, *C. callosum Sanderæ*, and many others of equal merit, besides a magnificent plant of *Ceologyne Dayana*.

Mr. W. H. White, grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, is to the fore with Orchids of botanical interest. The stand is one of considerable size, and many of the specimens are quite unique. Though several of these are not of particular beauty, they create a wonderful amount of interest, and their place at the Temple would be difficult to fill if the loyal President of the Royal Horticultural Society were to cease showing. Visitors never seem to become tired of examining such plants as *Epidendrum Mooreanum*, *Aëranthus zygopetaloides*, *Disa racemosa*, *Epidendrum Endresi*, *Stenoglottis longifolia alba*, *Oncidium pubes*; while *Cypripediums Euryale*, *Swannianum superbum*, *Eleanor superbum Lawrenceanum*, *ciliolare*, *Mastersianum*, *Stonei magnificum*, *Curtisi*, *Fraseri*, *bellatulum*, *niveum*, and *barbatum*; *Oncidium concolor*, *Odontoglossums citrosum*, *crispum*, *vexillarium*, *Halli*, *Andersonianum*, and *mulus*; *Dendrobiums polyphlebium Emerici* and *Bensoniae*; *Cattleyas Mossiae* in variety, *Skinneri*, *Mossiae Wagneri*, and *labiata Mossiae*; *Laelia purpurata*, *Thunias Brymeriana* and *Marshalliana*, superb *Masdevallias* provided flowers in varying forms and colours that are so necessary to the effective display.

The majority of horticulturists would in all probability designate Mr. Geo. Wythes, gardener to Earl Percy, Syon House, Brentford, a vegetable and a fruit grower alone; but those who visit the show during the three days that it will be open will see Orchids such as would be a credit to a specialist. There are, amongst others, *Laelia purpurata*, *Vanda teres*, *Cymbidium Lowianum*, *Laelia tenebrosa*, *Brassia verrucosa*, *Miltonia vexillaria*, *Dendrobium phalaenopsis Schroderiana*, *Thunia alba*, *Dendrobium chrysotoxum*, *Cypripedium Lawrenceanum*, *C. Sedeni candidulum*, *Dendrobium thysiflorum*, and beautiful forms of *Cattleya Mossiae*, all of which are displayed in an artistic manner. To aid in making the Orchids more prominent small Palms and Ferns have been judiciously employed.

Odontoglossums as staged by Wellbore S. Ellis, Esq., Hazelbourne, Dorking, are surprisingly beautiful, and show what good culture, combined with good taste will effect. Many of his varieties of *O. crispum* are good, but unfortunately the specific names could not be read. Besides these Mr. Ellis has staged *vexillarium*, *citrosum*, and a few others.

Mr. E. Carr, gardener to W. A. Gillett, Esq., Fair Oak Lodge, Bishopstoke, Hants, exhibits a collection of Orchids, amongst which the splendidly grown plants are finely flowered. The growths are clean and the colours in the blooms very clear. *Odontoglossums vexillarium* in variety, *crispum* in charming selection, fine *citrosum*, *Pescatorei*, and *maculatum*, *Laelia purpurata* of good form, pale and deep *Cattleya Mossiae*, with *Cypripedium niveum*, and others. Small Ferns as a groundwork enhance the general effect.

Brightly beautiful is the arrangement of Mr. W. N. Young, Orchid

grower to Sir Frederic Wigan, Clare Lawn, East Sheen. The abundant flowers are very pure in colour, of good shape and splendid substance, proving good culture. There are of more than common merit *Cattleya Mossiæ*, *C. Mendeli*, *C. Lawrenceana*, *Miltonia vexillaria*, *Cypripedium lævigatum* and *Lawrenceanum*. *Odontoglossum* Golden Sheen, crispum in variety, *Pescatorei*, and *Wilckeanum*, *Phalenopsis grandiflora*, *Aërides Fieldingi*, *Cattleya superba*, *Dendrobium Parishii* and *Dearei*, *Cattleya Skinneri virginalis*, *Dendrobium McCarthiae*, *Cymbidium Lowianum*, and *Cypripedium Gertrude Hollington*, all effectively staged.

Mons. A. Piret, Argenteuil, shows *Cattleyas Mossiæ alba*, *M. a. vestalis*, *M. a. variabilis*, and others. Mr. King, gardener to R. Brooman White, Esq., Ardarroch, shows a superb form of *Odontoglossum crispum* named *Starlight*. It is a variety of the first merit. Mr. Peeters Brussels, shows *Miltonia vexillaria virginale*, *Odontoglossum crispum* *Petersi*; and Mr. P. Blair, gardener to the Duke of Sutherland, Trentham, *Odontoglossum crispum* *Princess of Wales*. Mons. Hye, Leysen, Ghent, is represented by several Orchids of merit.

The arrangement of exhibiting adopted by Messrs. Lucien Linden, Brussels, cannot be said to be particularly elegant, there being far too

The metropolitan area is worthily represented in the Orchid section of this magnificent show, and Messrs. W. L. Lewis & Co., Southgate, contribute in a most praiseworthy manner. They are showing *Oncidium varicosum Rogersi*, *Lælia purpurata bella*, *Oncidium macranthum*, *Cypripedium Gertrude Hollington*, *Miltonia vexillaria*, *Cattleya Mossiæ Perfection*, *Lælia purpurata Millsiana*, *Cattleya Mossiæ* in variety, *Cypripedium Aylingi*, *Cattleya Mendeli Madonna*, *Masdevallia Harryana*, *Lycaste Deppei*, and *Lælia purpurata Rossiana*.

Mr. J. Clarke, gardener to Ludwig Mond, Esq., The Poplars, Avenue Road, Regent's Park, is represented by a small stand of Orchids, comprising *Cœlogyne Dayana*, *Odontoglossum citrosum*, *Lælia purpurata*, *Cattleya Mossiæ*, *Epidendrum vitellinum majus*, and *Odontoglossum crispum*. Interspersed amidst the Orchids are small *Ferns* and *Asparagus*.

Odontoglossums are the backbone of the exhibit from Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs. These are *O. crispum waltonensis*, *O. c. Annie*, *O. excellens Thompsoni*, *O. Wilckeanum elegans*, *O. W. nobilior*, *O. luteo-purpureum hystrix*, *O. sceptum aureum*, and some well-grown plants of the beautiful

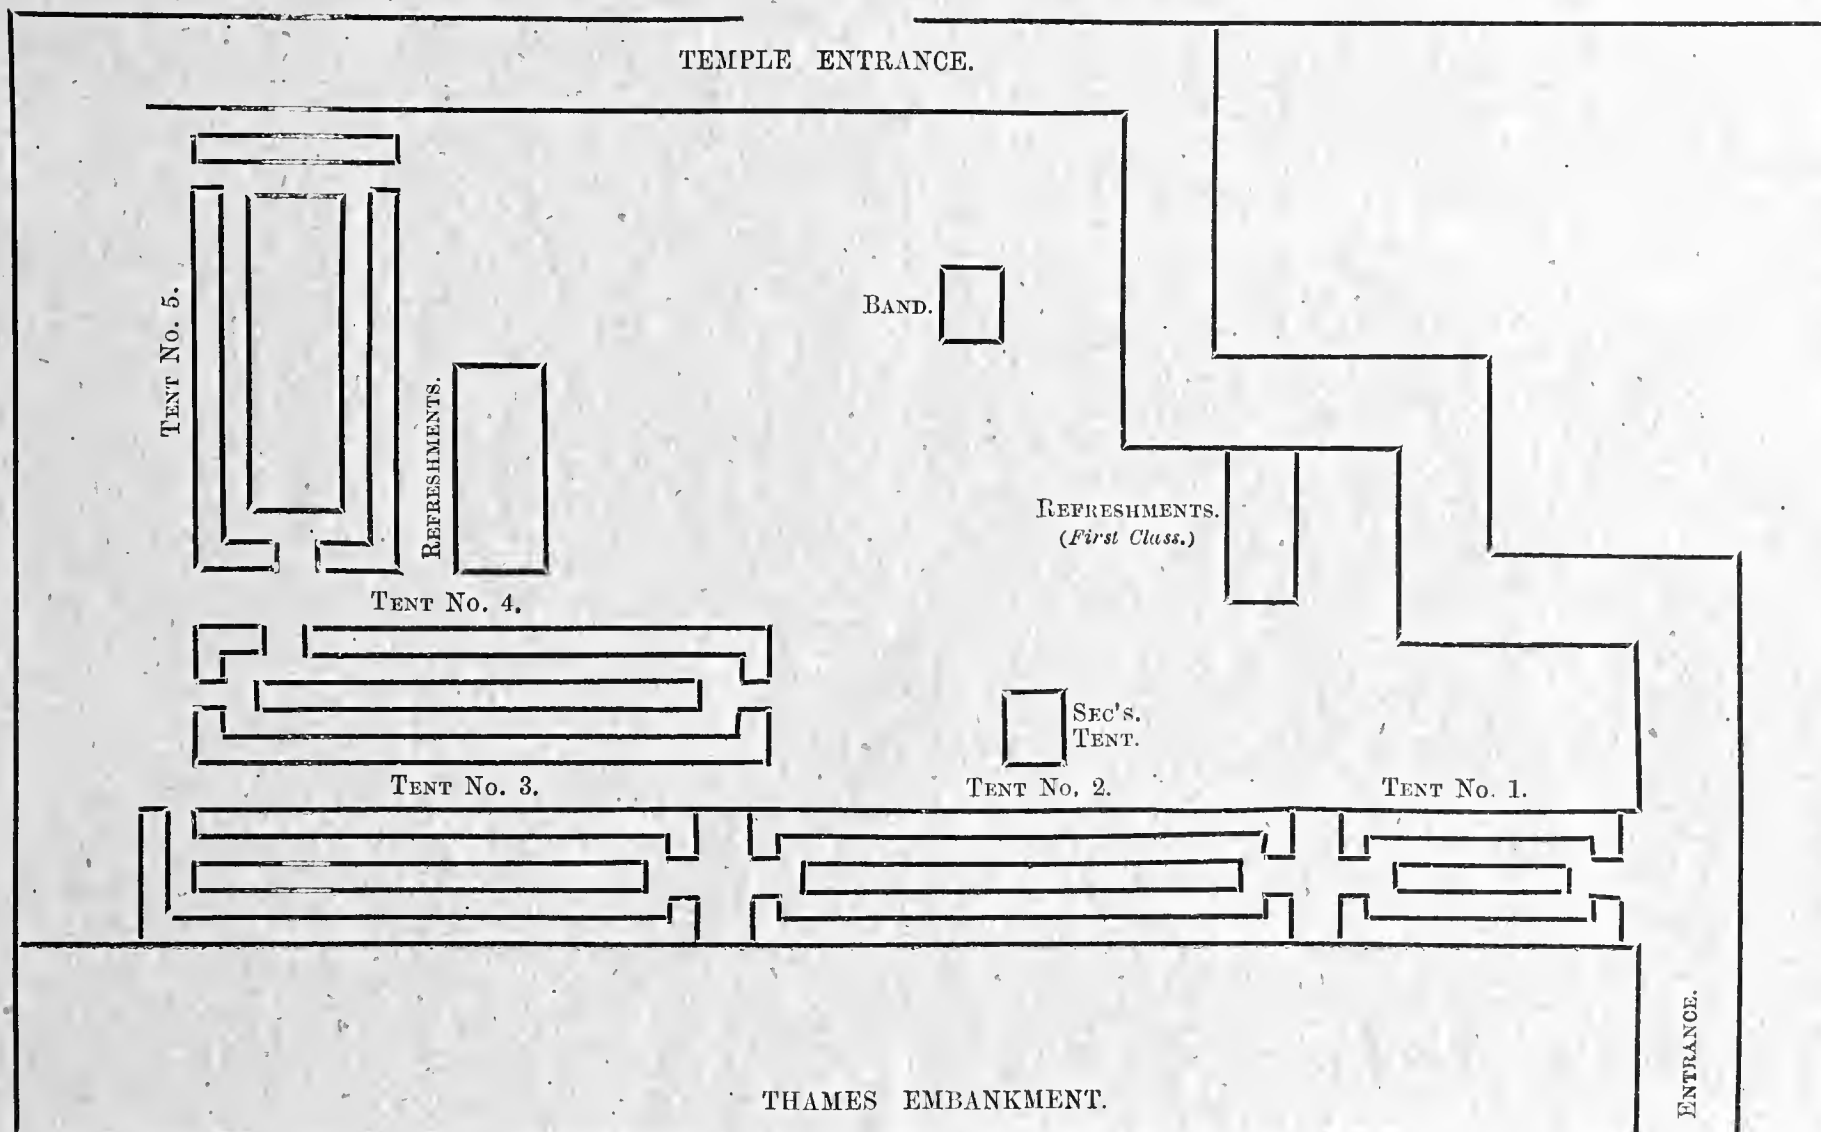

FIG. 90.—PLAN OF THE R.H.S. FLOWER SHOW, INNER TEMPLE GARDENS, MAY 26TH, 27TH, AND 28TH.

much furnishing moss on view. The plants are good, and the flowers are excellent, the effect being considerably minimised by the system of staging just referred to. Particularly good are *Cattleya Mossiæ coerulescens*, *C. M. formosa*, *C. M. Princess of Wales*, *C. M. Mathoniae*, *C. M. Empress Queen*, *C. M. flammea*, *Odontoglossum crispum*, *President Faure*, *O. c. Reine des Belges*, *O. Pescatorei Imperiale*, together with other varieties of great beauty.

Mr. T. Stafford, gardener to Fred Hardy, Esq., Tyntesfield, Ashton-on-Mersey, has a small collection of Orchids, in which quality largely preponderates over quantity. Prominent amongst others are *Cattleya Schilleriana*, Hardy's variety, *C. Mossiæ*, *Lælia purpurata Backhousiana*, *Odontoglossum vexillarium punctatum*, *O. citrosum*, *Cypripedium callosum Sanderæ*, *C. Goweri magnificum*, *Odontoglossum crispum*, and *Dendrobium Bensoniæ*.

Messrs. Charlesworth & Co., Heaton, Bradford, are represented by a very beautiful collection of Orchids, all of which have been splendidly grown. There are flowers of delicate hues and others of the richest and most decided colours on strong, healthy specimens effectively staged. *Cymbidium Lowianum*, *Lælia purpurata*, *Cœlogyne pandurata*, *Cattleya Mossiæ marginata*, *Odontoglossum crispum magnificum*, *Dendrobium Bensoniæ*, *Odontoglossum Pescatorei*, *L'immaculée*, *O. P. Burkinshaw's variety*, *Lælio-Cattleya Lady Wigan*, *Odontoglossum excellens*, *Lælia L. L. L.*, *Brassia maculata grandiceps*, *Odontoglossum crispum The Prince*, *Epidendrum vitellinum majus*, *Cypripedium barbatum*, and *Odontoglossum vexillarium* are very fine.

Cochlioda Noezliana. Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Cambridge Lodge, Camberwell, shows *Cypripediums Chapmani*, *C. C. magnificum*, and *C. Rhembka*, all hybrids of merit.

If there had been a few more flowers at the disposal of the arrangers, Messrs. J. Backhouse & Son, York, would have had one of the most effective exhibits in the whole exhibition. As it is the idea is a charmingly original one, but the highest effectiveness is lost for want of flowers. *Sobralias*, *Odontoglossums*, *Cypripediums*, *Cattleyas*, *Miltonias*, *Thunias*, *Azaleas*, *Lælias*, with *Palms*, *Ferns*, and other foliage and flowering plants are cleverly utilised in the combined arrangement.

A few Orchids are shown by Mr. F. J. Thorne, gardener to Major Joicey, Sunningdale Park, comprising *Miltonia vexillaria*, *Dendrobium formosum giganteum*, and *Anguloa Clowesi*, all magnificently grown. Messrs. J. Cripps & Son, Tunbridge Wells, send two pans of *Cypripedium caudatum*.

ROSES.

If any evidence is yet wanting of what can be done with a Rose tree in a pot, it may be obtained by a visit to the Temple Gardens. Those who saw the first show ten years ago will doubtless notice some of the same varieties to-day as figured conspicuously then, but they will also see marks of advancement in the Rose world. No *Crimson Ramblers* displayed their sprays of brightness at the first Temple Show, and though the praises of Mr. C. Turner's introduction have oft been sung, it is not too much to say it is distinct among the many features of the

exhibition. There are Ramblers formed in arches, and Ramblers as standards, while one also notices them as bright clusters of bloom on dwarf plants.

The exhibit of Messrs. Paul & Son, Cheshunt, is formed of superb examples of Mrs. John Laing, small standards of Crimson Rambler, with *Maréchal Niel* (white and yellow), Ulrich Brunner, *Violette Bouyer*, Marchioness of Londonderry, Juno, Beauty of Waltham, and the new Carmine Pillar. Standards of Madame de Watteville and others are dotted here and there in the extensive group which occupies a capacious corner. The large plants are so arranged as to present an undulating surface, and the whole displays the numerous pleasing forms in which Roses may be cultivated in pots, and does the Cheshunt firm great credit.

Four hundred square feet is a large place to make beautiful with pot Roses, but Mr. Chas. Turner, Slough, has done it; and done it in a way that is creditable to him. Only light coloured and crimson varieties are used, and these blend in happy harmony. Crimson Rambler, already referred to, forms the sum total of brightness, and other varieties set it off to advantage. As arches, standard and dwarf specimens is the beauty of the Rambler fully seen, and intermingled with it are superb plants of Mrs. John Laing, Ulrich Brunner, Juno, Celine Forestier, Edith Gifford, La France, Marchioness of Londonderry, Madame Lacharme, *Violette Bouyer*, Camille Bernardin, and *Perle d'Or*. This mass of Roses is broken in outline, and in the arrangement the art of a decorator is apparent.

Messrs. William Paul & Son, Waltham Cross, have a splendid group of Roses near to the entrance of the big tent. Crimson Rambler is well displayed in pots, as also are Crimson Queen, *Merveille de Lyon*, Mrs. John Laing, *Gloire Lyonnaise*, *Triomphe de Caen*, Ulrich Brunner, Caroline Testout, Spenser, Her Majesty, Danmark, and Caroline Testout. Among the cut blooms are several charming novelties, including Empress Alexandria of Russia (quite a new colour), Medea, White Lady, and Enchantress. Then there are fine blooms of such popular favourites as *Maréchal Niel*, Clio, Victor Verdier, Jean Ducher, and Fisher Holmes. Over eighty varieties are included in the group, which is altogether of superior merit.

Mr. W. Rumsey, Waltham Cross, is represented by Roses of fine quality. The plants of medium size are well suited for arranging on a table, and it would be difficult to give too much praise to the specimens of Crimson Rambler, Climbing Earl of Pembroke, Mrs. Rumsey, La France, Climbing Star of Waltham, Madame de Watteville, *Souvenir d'un Ami*, Magna Charta, Edouard Morren, Grace Darling, Peach Blossom, and Albert Page. Along the front are cut blooms in pleasing variety, including *Maréchal Niel*, Niphetos, Ulrich Brunner, Charles Lefebvre, Beauty of Waltham, The Bride, Dr. Andry, Baroness Rothschild, Madame Victor Verdier, and *Souvenir d'un Ami*. Taste in arrangement is everywhere apparent in the formation of this group.

Mr. G. Mount's Roses are well known to visitors to the Royal Horticultural Society's meetings, but to-day the famous Canterbury grower has surpassed his former efforts. His plants of Crimson Rambler are simply magnificent, and arranged along the back of the stands of cut flowers they have a most charming effect. Cut blooms are no less meritorious. Noticeable amongst others are Madame Gabriel Luizet, Catherine Mermet, Niphetos, Mrs. John Laing, The Bride, Ulrich Brunner, Duke of Wellington, Caroline Testout, Lady Mary Fitzwilliam, La France, Charles Lefebvre, Jean Ducher, Earl of Dufferin, Anna Olivier, and Annie Wood.

PLANTS AND FLOWERS.

Entering the large marquee at the Temple entrance the visitor's attention is at once directed to the fine exhibit from the nurseries of Messrs. Wills & Segar, South Kensington. The firm maintains its high reputation for decorating, and set in the group in artistic form are rare plants, including *Alcassia Rodrigueziana*, *Dracena Goldiana*, *Heliconia illustris*, *Anthurium crystallinum*, *Aralia nymphaefolia*, *Alocasia metallica*, *Phrynium variegatum*, and *Kentia Canterburyana*. A margin along the front is formed of *Selaginella*, and tastefully interspersed amongst the Palms and fine-foliage plants are Ferns in pleasing variety, the whole making up a charming group.

There is little need to inquire whence come the Clematis which form a distinct feature adjoining the above exhibit. They are old acquaintances at the Temple Show, and this year Messrs. Richard Smith and Co. of Worcester show quite up to their usual standard. This means that they are excellent, and diversity is formed by fine trained specimens comprised of such varieties as Lord Derby, Blue Gem, Marie Lefebvre, Sensation, Mrs. George Jackman, Princess of Wales, Countess of Lovelace, Lawsoniana, and *Gloire de St Julien*. Whites, blues, and purples are included in the foregoing, and again the Worcester Clematis are living examples of the beauty of this plant when grown under such conditions.

Near at hand is a group of plants staged by Mr. W. Iceton, Putney, in which are to be seen examples of good culture and taste in arrangement. The background is formed of elegant Palms and Acers, interspersed with small groups of *Lilium Harrisii*. Then come clumps of *Azeala mollis*, and masses of Lily of the Valley peeping from a thicket of Maidenhair Ferns. Any tendency towards flatness is done away with by Caladiums, Crotons, Dracenas, Ficus, and Pandanus which stand up above the ground line, and in every plant may be noticed the signs of high quality and good culture.

At no other show in the country are Caladiums represented in such excellence and variety as at the Temple. This year there is further proof of it, and the group staged by Messrs. J. Laing & Sons, Forest

Hill, is well worthy of the firm's reputation. Plants with huge leaves form the background, and tapering down to the front they gradually decrease in size. Not so in quality and brightness of colouring, which are unique throughout. Conspicuous in the exhibit are candidum, Mrs. Harry Veitch, Rose Laing, C. E. Dahle, Botafoyo, Baron Adolphe de Rothschild, L'Insolite, Charlemagne, F. W. Moore, George Berger, Louis Van Houtte, ornatum, and B. S. Williams.

Forming a pleasant break between two gorgeously tinted masses of Caladiums is a diversified group from Messrs. Jas. Veitch & Sons, Chelsea. This is formed chiefly of trees and shrubs of a hardy character, and comprises the showy spikes of *Eremurus himalaicus*, masses of *Hydrangea paniculata grandiflora*, the contrasting tints of Azaleas in variety, Paeonies of many hues, with *Wistaria sinensis*, *Lilium longiflorum Harrisii*, Lily of the Valley, *Cytisus purpureus*, *Daphne cneorum majus*, *Spiraea astilboides floribunda*, and others. Acers in variety are dotted here and there, giving the whole a light and elegant appearance.

Then again Caladiums, this time from Messrs. J. Peed & Sons, Norwood, who have long since made themselves famous as growers of these elegant foliage plants. Quality and variety are unmistakable characteristics of the group, the plants being set up with taste. A groundwork of *Adiantums* shows off the richly coloured leaves to advantage, and among the numerous varieties are candidum, Prince of Wales, Le Nain Rouge, Michel Buchner, Baron Adolphe de Rothschild, Rose Laing, Gerard Dow, and Ibis Rouge. Among the Diamond Jubilee introductions are Mrs. John Peed, Duchess of Teck, Henry Dixon, Maria Dabil (very distinct), Thomas Peed, and Mr. W. H. Cumings, all of which are dwarf of habit with small rich leaves.

One corner of the tent is admirably filled by Messrs. W. Cutbush and Son, Highgate, and it would be difficult to speak too highly of the display of Carnations staged. The background is formed of Palms and other foliage plants, and in front of these is an undulating bank of the flowers named. Amongst the varieties are Germania, Lady Grimston, General Stewart, La Villette, Andrew Noble, Reginald Godfrey, and Cardinal Wolsey. Malmaisons form the majority of the display, and grouped *en masse* they make a fine effect, but had the show been a week later hundreds of the present buds would have been open flowers, by which the beauty of the exhibit would have been further enhanced.

There is a stamp of quality about the Caladiums staged by Messrs. Jas. Veitch & Sons, which is easily discerned, the plants being large, compact, and with leaves of a leathery character. Sloping gracefully in bank-like form, and interspersed with Maidenhair Ferns, the diversified tints are shown to advantage. Huge specimens of Madame John Box, Alice Van Geert, George Berger, Mrs. Harry Veitch, and Gaspard Crayer are very conspicuous; while of more diminutive habit are Silver Cloud, F. W. Moore, Princess Royal, Avillon, Lady Stafford Northcote, Baroness Schröder, Mrs. Bause, Exquisite, Prince Edward, Leonard Bause, Her Majesty, Duke of York, Chelsea Gem, Ladas, Lord Penryhn, and Martha Laforge, several of which are new.

Contrasting pleasingly with the gorgeous array of Orchids that graces the centre table of the large marquee is at one end a small but effective exhibit from the nurseries of Messrs. John Waterer & Son, Bagshot. This is formed of hardy Rhododendrons of various hues, comprised of Michael Waterer, J. H. Agnew, Mrs. Wm. Agnew, John Waterer, Charlie Waterer, Marchioness of Lansdowne, Duchess of Connaught, Duchess of Bedford, Star of Windsor, Kate Waterer, B. W. Currie, Mrs. Holford, and Chionoides. All the plants are covered with bloom, and many of the trusses are remarkable in size.

Mr. Thos. Whillans, gardener to His Grace the Duke of Marlborough, Blenheim Palace, Woodstock, shows his skill as a Carnation grower in his exhibit of these flowers, which are arranged at the other end of the long Orchid table. The blooms of *Souvenir de la Malmaison* Princess of Wales are of extraordinary size and stability, and high praise is accorded to the new yellow Carnation Duchess Consuelo, the plants of which are taller, crowned with flowers and foliage of that bright green hue which foretells good health.

Two hundred and fifty square feet of tabling are occupied by Mr. H. J. Jones' exhibit of Begonias. To say that these are the cream of the famous Lewisham collection gives a good idea of the excellence and diversity of the exhibit, the chief characteristics of which are variety and size of bloom, sturdiness of habit, and stability of foliage. The surface of the bank rises and falls, thus breaking the stiffness that might otherwise have been apparent, and Ferns are judiciously blended in the arrangement. Every colour known in Begonias is represented, both in double and single forms. Some are delicate in tint, others of a bold striking hue, while, to sum up briefly, all are of excellent quality, and equal if not superior to anything that Mr. Jones has shown before.

The next exhibitor's card bears the name of Messrs. John Laing and Sons, Forest Hill, whc, it is almost needless to add, show Begonias of the highest quality. Many of the varieties staged owe their origin to the firm, and amongst them one notices beautiful doubles of crimson and yellow shades, singles pure white, and of immense size, singles yellow, and singles scarlet. Amongst the named sorts are Duchess of Marlborough, an immense double of delicate flesh tint; Diamond Jubilee, a charming canary yellow; Clio, of similar colour, with edges of petals delicately fringed; and Dr. Jim, a striking light crimson. The arrangement is pleasing, and the plants throughout carry a stamp of exceedingly high quality.

Mr. G. Hunt, gardener to Pantia Ralli, Esq., Epsom, does himself credit in the exhibition of a good display of Caladiums. Amongst other varieties are Sir Julian Goldamid, Duchess of Fife, William Marshall, Madame John Box, Rose Laing, B. S. Williams, Reine de Denmark, Silver Cloud, Baron Adolphe de Rothschild, John Laing, Marquis of

Camden, Sir Henry Irving, and Mrs. Harry Veitch. Considering the display is from a private establishment it is a very meritorious one.

Clematis from Messrs. Geo. Jackman & Sons, Woking, make themselves seen by their healthy appearance and covering of varied floriference, and are comprised of Countess of Onslow, Duchess of Albany, and Duchess of York. The firm also has a fresh display of hardy flowers in variety. Conspicuous in the collection are *Primula luteola*, *Pæonies*, *Pyrethrum Hamlet*, *Papavers Blush Queen* and *orientalis bracteata*, *Phlox G. F. Wilson*, *Aster alpinus superbus*, double white Rockets, and other well known members of the hardy section.

A group of *Calceolarias*, bright and effective, hails from the nursery of Messrs. J. James & Sons, Slough. The plants bear traces of good culture in their dwarf sturdy habit, surmounted by masses of gaudily hued flowers. How to grow good *Calceolarias* of dwarf habit puzzles many admirers of these plants, but Messrs. James have apparently learned the secret, as in this respect the exhibit was exceptionally striking.

Messrs. Cannell & Sons, Swanley, have made a gallant display, which to see is to admire. What this well-known firm can do with *Cannas* needs no republishing; yet this section of the exhibit forms splendid evidence of their skill in the cultivation of these bright-hued flowers. Amongst the varieties are *Sunset*, *Queen Charlotte*, *Progression*, *Henry Irving*, *Paul Brnant*, and *Italia*. Next come *Gloxinias* in charming variety, the most conspicuous of which are *Prince of Wales*, *William Marshall*, and *Petunia*. Double *Begonias* claim a special word of praise, many of the varieties being exceptionally fine, though a little too close in arrangement. *Calceolarias* are extremely showy, and form a mass of varied blooms. Growth and habit are quite of the Swanley stamp, and the large exhibit throughout displays a striking diversity.

Japanese *Acers* of a varied character are staged by Messrs. Cripps and Sons, Tunbridge Wells, and show the elegance of these plants to great advantage. Bright green is the colour of *Acer japonicum aureum*, and as a contrast to this the copper-tinted hue of *A. palmatum atro-purpureum* is very pleasing. The foliage of *A. palmatum palmatifidum* is extremely graceful, and the same may be said of *A. palmatum dissectum*, and *A. palmatum linearilobum*. *A. palmatum florescens* is of light character in foliage, and of graceful habit, and other plants in the exhibit are equally striking.

Messrs. W. Fromow & Sons, Chiswick, are represented by Japanese Maples, amongst which are interspersed plants of *Lilium Harrisii*. Conspicuous in the group are *Acers palmatum tricolor*, *dissectum purpureum*, *palmatum roseum marginatum*, *japonicum laciniatum*, and *japonicum aureum*. *Aralia pentaphylla variegata* is included in the exhibit, which is diversified in character and arranged to good advantage. Many people are not aware of the beauty and usefulness of the hardy Japanese Maples which are so well shown by the Chiswick firm.

Extremely interesting is the exhibit of Messrs. W. Balchin & Sons, Brighton, which is comprised of hardwood plants. In the centre is a splendidly flowered plant of *Erica Spenceri*, and round it run the graceful forms of *Boronia serrulata*. *Boronia heterophylla* are arranged at the corners, and contrast pleasingly with the rich yellow of *Erica Cavendishi* and the unique blue tint of *Leschenaultia biloba major*. Well-flowered plants of *Genetyllis tnlipifera* and *Pimelea decussata* are conspicuous in an exhibit which is admirably arranged, and composed of plants of an interesting and beautiful character.

Messrs. R. & G. Cuthbert, Southgate, have a tasteful exhibit, comprised of Azaleas in great variety. Amongst others are *Pallas*, *Anthony Koster*, *Tasso*, *Prince Baudouin*, *Phidias*, *Mignon*, *Mons. Desbois*, *Aida*, and *Mr. E. Gumbleton*, the whole giving a good idea of the beauty of these flowers.

Ferns and foliage plants in variety comprise the exhibit from the nurseries of Mr. H. B. May, Edmonton, and are arranged with much taste. Noticeable among many others are *Platyterium æthiopicum*, *Polypodium glaucum*, *Gymnogramma chrysophylla grandiceps*, *Adiantopsis radiata*, *Davallia Mariesi maxima*, *Adiantums farleyense* and *fragrantissima*, *Polypodium aureolatum*, *Pterises longifolia Mariesi* and *tremula densa*. Other pleasing forms are noticeable, illustrating the extensiveness of Mr. May's collection.

New and rare plants of surpassing beauty come from Messrs. F. Sander & Co., St. Albans. These include specimens of a new double *Petunia*, *Mrs. Fred Sander*, and a fine plant of *Davallia hirta*. *Dracæna Sanderiana* figures conspicuously in the exhibit, which also contains *Streptocarpus Sander's White*. *Dracæna Godseffiana* is remarkably well shown, as also are *Anthuriums* in variety, *Begonias* of velvety foliage, and *Caladium speciosum*. Standing at one end of the group the visitor sees *Pitcher Plants* and *Flame Flowers*, *Begonias* and *Orchids*, *Petunias* and tiny cluster *Roses*, with foliage plants and Ferns of diversified character all blended together, and forming contrasts that are, in short, both elegant and graceful.

Dotted in between two masses of showy *Orchids* is a group of well grown *Gloxinias* from the nurseries of Messrs. J. Peed & Sons, Norwood. In the centre is a mass of *Beacon*, a showy crimson variety, and striking also are the flowers of *Jumbo*, *Mrs. Burrell*, *Duke of York*, *John Peed*, and *Aigburth Crimson*. The plants, though not large, are of compact habit, with abundance of flowers surmounted on sturdy footstalks.

Messrs. W. & J. Brown, Grantham, occupied a small square of space with a varied collection of plants, comprising *Crimson Rambler Roses*, *Kalosantes*, *Mrs. Wynne*, *Zonal Pelargoniums* in variety, with *Begonias* and *Mignonette*, interspersed with Ferns and foliage plants.

Outside one of the tents is an interesting group of plants from *Leopold de Rothschild, Esq., Gunnersbury House*. Included in it are immense specimens of white *Marguerites*, the equal of which are rarely seen, scented *Geraniums* several feet through, pyramids of equal merit,

and *Myrtles* that give evidence of superior culture. Mr. Hudson's exhibit is worthy of his skill as a gardener, and is particularly interesting, inasmuch as it is an entirely new feature. Perhaps few people are aware of the splendid specimens that may be formed of a common *Marguerite*, and in this respect the exhibit is a means of education.

Messrs. J. Backhouse & Sons, York, again have their miniature rockery, on which are shown Alpines in a growing state. To bring a rock garden under canvas is something out of the ordinary, but so well is it done that there is little about it that looks artificial, and it is an admirable way of showing the beauty of many of the tiny gems. Among other charming rock plants are *Myosotis Rhosteineri*, *Viola lutea Gem*, *Gentiana verna*, *Armeria Lauchiana*, *Antbyllis montana rubra*, *Linum alpinum*, *Phlox subuluta compacta*, *Saxifragas cochlearis* and *atro-purpurea*. The firm also shows *Carnation Marjorie Pierce*, a pleasing tint of yellow, and other flower and foliage plants.

Messrs. Barr & Sons, Covent Garden, have their usual large exhibit of hardy flowers quite up to the reputation of the firm. Irises are the first to claim attention, and amongst these *I. pallida Albert Victor*, *I. albicans Princess of Wales*, *I. germanica Kharput*, and *I. variegata Abou Hassan*, are very striking. Then comes a small space formed as a rock garden, containing the charming flowers of *Saxifraga Macnabiana*, *Phlox Nelsoni*, *Viola pedata*, *Myosotis rupicola*, *Lychnis alpina*, *Trollius Orange Globe*, *Dodecatheon splendens*, *Aubrietia Leitchlini*, and many others. The mass of hardy flowers is confusing in variety. There are *Papavers* and *Pæonies* of many tints, *Pyrethrum* of bright colour and numerous varieties, florists' *Talips*, *Centaureas*, *Thalictrums*, *Ixias* of divers hues, beautiful *Carnations*, *Anemones*, *Gypsophila elegans*, *Lupins*, and *Narcissi*, with many others, which make up a unique display.

A pleasant break in the masses of floral beauty all round is the miniature rockery set up by the Guildford Hardy Plant Company. It is admirably furnished by members of the Alpine family, and from crevices in the stones peep out such gems as *Saxifraga Wallacei*, *Phlox Vivid*, *Cypripediums calceolus*, *montana*, and *pubescens*, and many others. For the benefit of visitors it would be well if the flowers were labelled, as this would add to the interest of the exhibit. Coniferous plants form a good background, and the display on the whole is extremely interesting.

Messrs. W. Paul & Son, Waltham Cross, are responsible for a varied exhibit, comprising a new single *Thorn Crimson Queen*, specimens of foliage plants, and a collection of *Rhododendron* flowers, among which may be seen *The Gem*, *Nero*, *John Waterer*, *Lady Dorothy Neville*, *Lord Palmerston*, *Frederick Waterer*, *Mrs. Standish*, *Portia*, *Mrs. Milner*, *Countess of Wilton*, *Charles Dickens*, *erectum*, *The Queen*, and *Nobleanum bicolor*.

Carnations in pots are staged by Mr. John Forbes, Hawick. These are composed entirely of the scarlet variety *Yuletide*, the blooms of which are large and well formed, while the plants illustrate the habit and usefulness of the variety. The firm is also showing a collection of seedling *Polyanthus*, illustrating its strain of these favourite spring flowers.

Herbaceous and other flowers are shown by Messrs. Paul & Son, Chess-hunt, comprising *Lilacs* and *Rhododendrons*, *Irises* in variety, *Papavers orientale coccineum* and *orientale*, *Geum miniatum*, *Centaureas montana* and *montana album*, *Lupinus polyphyllus albus*, *Pyrethrum Hamlet*, and others, the whole forming a diversified exhibit. Edwardian decorations come from Messrs. W. Edwards & Sons, Sherwood, Nottingham, who have a table stocked with elegant arrangements of Ferns and flowers.

The delicate green of Ferns contrasts pleasingly with the wealth of flowers, and for this Messrs. W. & J. Birkenhead, Sale, are chiefly responsible. Their exhibit is a large and varied one, comprising stove, greenhouse, and hardy Ferns. There are *Adiantums coccineum*, *speciosum*, *grandiceps*, *farleyense*, *tenerum*, *roseum*, *intermedium*, and others; *Polystichums cristatum*, *aculeatum*, *venustum*, *congestum*, and *divisilobum densum*, *Athyriums* in great variety, and *Pterises tremula*, *Smithiana*, *Wimsetti*, and others. Under the cover of a glass case is a pleasing variety of "Filmies," including *Todea superba* and *Trichomanes radicans*. Giant Elk's-horns contrast strikingly with the diminutive and graceful growths of many of the more tender forms, and the exhibit is of interest to all visitors.

A long extent of tabling is occupied by Messrs. Kelway, Langport, who show *Pyrethrus* in charming variety, numerous flowers of *Amaryllis*, including *Ziska*, *Mrs. Langtry*, *Alfred Henderson*, and *Wilkie Collins*, and *Cannas* of varied hues. In addition to these the firm has large stands of *Aquilegias*, *Lupins*, *Pæonies*, and *Irises*. Double *Pyrethrus* are in themselves a feature, and illustrate the usefulness of these charming flowers. Among the latter *Wilson Barrett*, *Melton*, *Evelyn*, *Nancy*, *Ne Plus Ultra*, *Leonard Kelway*, and *Queen Sophia* are well worthy of special mention, though the exhibit altogether is quite equal to former attempts of the firm.

Messrs. A. W. Young & Co., Stevenage, have an exhibit comprised of a variety of plants and flowers. *Coleus* are side by side with *Pansies*, and near at hand are *Wallflowers* and *Rhododendrons*. Further on are hardy flowers and rock plants in variety, and further still a collection of semi-double salmon-tinted *Zonal Pelargonium King of Denmark*. Attempts have evidently been made to get a large number and variety of plants into a limited space, and in this respect Messrs. Young have succeeded thoroughly.

Alpine and hardy herbaceous flowers occupy the space allotted to Mr. M. Pritchard, Christchurch, Hants. One notices the blooms of *Hemerocallis flava*, *Trollius japonicus*, *Pæonias* in variety, *Thalictrum*

aquilegifolium roseum, *Pyrethrum Florentina* and *Niveum plenum*. *Aquilegias* of mixed strains, *Phloxes divaricata* and *The Bride*, *Delphinium Belladonna*, *Lupinus arboreus*, *Eurybia Ganniana*, *Anthericum liliastrium*, *Geum miniatum*, and others. The flowers are arranged with taste, and not unduly crowded.

Messrs. J. Chcal & Sons, Crawley, are responsible for a diversified exhibit of rock plants, flowering shrubs, and *Violas*. Amongst the latter are *Archie Grant*, *Bridesmaid*, *Crimson King*, *Trentham Purple*, *Ardwell Gem*, *Blush Queen*, *Bullion*, and *Colleen Bawn*. Following these is an artistic rockery* furnished with *Phloxes* of many varieties, *Cheiranthus alpinus*, *Aubrietia Leitchlini*, *Veronica rupestris*, *Lithospermums prostratum* and others, this part of the exhibit being followed by hardy foliage and flowering shrubs, including *Acers*, *Genistas*, *Lilacs*, *Rhododendrons*, perhaps a little too crowded in arrangement.

Those whose taste leads them in the direction of the ever-popular *Sweet Pea* may find them in the exhibit of Messrs. Dobbie & Co., *Rothsay*. *Dahlias* in May are quite extraordinary, yet this enterprising firm has them in such varieties as *Miss Webster*, *Earl of Pembroke*, *Cannell's Gem*, *Matchless*, *Countess of Pembroke* of the *Cactus* types, and singles *Kenilworth*, *Lady Rowena*, *Alice Lee*, and *Anne of Geirstein*. Turning to the *Violas* the visitor's interest is centred on such charming varieties as *Blue Cloud*, *Rob Roy*, *White Bedder*, *Iona*, *Wonder*, *Lavender King*, *Dandie Dinmont*, *White Flag*, *George Lord*, *Peter Barr*, *Ardwell Gem*, *George Abbey*, *Prince of Orange*, *Lemon Queen*, *True Blue*, and others, all in the pink of perfection.

Mr. J. R. Box, Croydon, has a group of *Begonias* quite up to his usual standard. Both double and single forms are well represented, the flowers in all cases being large, and plants of healthy sturdy character. Amongst the former the blooms of *Diamond Jubilee*, *Princess of York*, and *Queen of Queens* are exceptionally fine, the latter being of a most effective colour. The single forms extend over a wide field of colour, and the exhibit is one of the best of its kind in the show.

Carnations also come from Mr. Geo. Stevens, Putney, who shows a diverse collection, which includes Mrs. Geo. Stevens, Mrs. Whittle, Miss L. Stevens, Ruby Primrose, and G. Pike. Mr. C. Blick, gardener to Martin R. Smith, Esq., The Warren, Hayes, has plants of a fine white *Carnation* called *Bondsman*, another one of the same colour, *Elfin*, and a border variety, *Artemus*. Mr. W. Bull, Chelsea, sends plants of *Ficus radicans variegata*, *Davallia epiphylla*, *Anemia rotundifolia*, and *Crinum Moorei variegatum*; and from Mr. Moser, Versailles, are plants of a pretty striped *Clematis Nelly Moser*. From Mr. H. Howell, Hammer-smith, there is a small but effective exhibit of *Ferns*, including *Pteris Howelli* and *Caladiums*. Mr. R. Dean Ealing, sends plants of new dwarf bedding *Violas* growing in pots, among which are included *Fascination*, *Hetty*, *Tiny*, *Dorothy*, *Regalia*, *Lavender*, *Ladas*, and *Little Tich*.

A pleasing collection of hardy flowers hails from Mr. B. Ladhams, the Shirley Nurseries, Southampton. Their appearance is fresh, and not overcrowded. Amongst many others *Heuchera sanguinea*, *Lupinus arboreus* and *arboreus albus*, *Centaurea montana rosea*, *Papaver orientale*, *Aster alpinus superbus*, *Senecio Doronicum*, with single and double *Pyrethrums* and *Irises* in variety, are very effective. From the Ichthemio Guano Company, Ipswich, is a collection of *Azaleas* and *Pelargoniums*. From Messrs. Gregory & Evans, Sidcup, are specimens of yellow *Calceolaria Victoria*.

Messrs. R. Wallace & Co., Colchester, are represented by a unique exhibit, which includes miniature hardy *Cypripediums*, snow white single *Pæony* Mrs. Robert Wallace, *Brodiaea capitata*, diminutive *Calochorti* in variety, and an elegant group of *Spanish Iris*. In addition to the above are *Liliums* of many kinds, including *umbellatum*, *Sappho*, *longiflorum giganteum*, *Dalhouseianum*, *tenuifolium*, and others. Graceful *Ixias* claim the attention of visitors, and another pretty flower is *Ixiolirion Pallasii*. *Camassia esculenta* is included in the group, and among the array of *Irises* are *lupina variabilis* *Raphael*, *Queen of May*, *florentina*, and *flavescens*.

Strikingly beautiful is the display made by Messrs. Jas. Veitch and Sons, Chelsea. *Phyllocactus* are in themselves a feature, but their beauty seems dimmed by the glorious array of *Gloxinias* and *Streptocarpus*. Among the former are to be seen fine plants of *Gomez*, *Eclatant*, *Adela*, and *Virginalis*, and others, and in the collection of the latter Mr. Heal, Messrs. Veitch's well known grower and hybridiser, does himself great credit. Amongst the hybrids shown are numerous shades of purple, violet, pink, and rose. Others are pure white, and in the exhibit one sees a perfection in *Cape Primroses* that were little thought of a few years ago, and the healthy appearance of the plants denotes high cultivation.

Messrs. Sutton & Sons, Reading, made a splendid feature with their large exhibit of *Gloxinias*. There are over 400 plants, remarkable for their floriferousness, colour, and erect habit. Among the diversity of forms are *Her Majesty*, a fine white variety; *Empress of India*, an imposing flower of rich purple; *Reading Scarlet*, which in colour is true to its name, and spotted hybrids, the delicate markings of which are worthy of close attention. The famous Reading firm occupies the greater portion of one of the middle tables with *Gloxinias*, following which a fine group of Sutton's Giant *Mignonette* tells its presence by the huge flowers and delicious odour. The plants are fine examples of good culture, being of compact and sturdy habit. On beds in the gardens are groups of Sutton's bedding *Begonias*, which well illustrate the usefulness of the strain for the adornment of flower gardens.

Messrs. Fisher, Son & Sibray, Sheffield, have a small exhibit of *Oroton* "*Her Majesty*," a graceful variety, with green and yellow foliage. Outside the tents the firm has a large group of plants, com-

prised chiefly of *Acers*, *Elders*, *Cornuses*, and *Euonymuses*. The plants are tastefully arranged, and though outside they are no less a feature.

Messrs. Jas. Veitch & Sons had a group of hardy flowering shrubs outside the tents, and Messrs. John Waterer & Sons, Bagshot, had an interesting group of Japanese *Maples*—dwarf plants of all the best varieties.

FLORAL DESIGNS.

In this section the palm is unreservedly given to Messrs. Jas. Carter and Co., High Holborn, who are to be commended for leaving the trodden path and introducing a new feature. The exhibit occupies the whole of the centre table in tent No. 1, and is remarkably fine. In the centre is a floral design, surmounted by a crown, and below this hangs a floral V.R., this being in close affinity to the *Diamond Jubilee*. *Asparagus plumosus* and flowers are judiciously employed, the result being a most effective arrangement. Underneath are magnificent *Calceolarias* of a superb strain, and following these one sees *Gloxinias*, *Petunias*, and *Mimuluses* of immense size of flower. *Lilium Harrisii* and *Shirley Poppies* stand at one end of the table, and further on are masses of the dwarf *Sweet Pea* *Cupid*, *Pyrethrums*, *Nasturtium Empress of India*, *Narcissi*, *Tulips*, *Lupines*, *Irises*, *Pansies*, and *Sweet Peas* in pots dotted about amongst vegetables of superb quality. In the exhibit the Holborn firm has surpassed any of its former efforts.

Mr. L. H. Calcutt, Stoke Newington, has floral designs in the form of wreaths, crosses, harps, arches, bouquets, and so forth. Choice flowers are displayed with taste, and elegant arrangements are the result. *Orchids* are used in conjunction with *Irises*, and white *Pancreatums* and scarlet *Carnations* also go together. Blue *Cornflowers* and scarlet *Geraniums* are largely used in the varied designs. Baskets of choice *Orchids*, bouquets of *Carnations*, harps of stove flowers, and designs of *Roses*, *Carnations*, and other flowers are admirably shown by Messrs. Jones & Sons, Shrewsbury. *Asparagus plumosus* is largely used, its feathery lightness blending pleasingly with the flowers. The whole is a splendid display of the florists' art, and is much admired. Miss May Foden, Hemel Hempstead, has a pleasing decoration for dinner table, formed of *Spanish Irises*, with *Grasses* and *Ferns*; and near at hand Mrs. W. Green, Romford, has made a pleasing arrangement with *Aquilegias*, *Smilax*, and *Marguerites* shown in elegant glass stands.

The exhibit of Mrs. Phippen, Reading, is extremely effective, though a little too crowded. In the centre is a huge cross of scarlet *Pelargoniums* and *Anthuriums*, and on either side are designs of *Roses* and other flowers, stars of *Lily of the Valley*, bouquets of *Orchids* and *Roses*, with lyres and harps of extreme beauty, and displaying much taste. Mr. H. C. Garford, Stoke Newington, has a large decoration of choice flowers and elegant foliage.

Mr. J. Prewett, Bayswater, W., shows floral designs, which illustrate ways of decorating a dinner table in an easy and effective manner. *Roses* and *Orchids* are principally used, with *Fern* and other light foliage. Moyses Stevens, Belgravia, has beautiful display of wreaths, crosses, and bouquets. Conspicuous in the exhibit of Messrs. Perkins and Sons, Coventry, is an immense crown, formed of yellow *Roses*, crimson *Carnations*, and *Ericas*, which is very effective. Baskets of *Roses* and *Orchids*, with bouquets and other designs of surpassing elegance on either side, are quite worthy of the high reputation of this firm.

CERTIFICATES AND AWARDS OF MERIT.

Anæctochilus Sanderianus (F. Sander & Co.).—A peculiarly pleasing colour is the leaf of this plant. The green is wonderfully bright, while the brown and rose venations are very conspicuous (award of merit).

Azalea rustica fl.-pl. Freya (J. Veitch & Sons).—A surprisingly floriferous variety of the best habit. The colour is rose, with a very slight suspicion of orange (award of merit).

Azalea rustica fl.-pl. Ribera (J. Veitch & Sons).—This is so free flowering that it is almost impossible to see the leaves. The colour is white suffused with rose (award of merit).

Begonia Diamond Jubilee (J. R. Box).—A pure yellow double variety of the best quality (award of merit).

Begonia Queen of Queens (J. R. Box).—A beautiful flower of a soft apricot colour (award of merit).

Caladium Lady Stafford Northcote (J. Veitch & Sons).—This is probably one of the best varieties in cultivation. The leaves are true crimson, and the habit of the plant is very good (award of merit).

Caladium Mrs. McLeod (J. Veitch & Sons).—Belonging to the dwarf section, this is one of the most charming in the show. The colour is crimson (award of merit).

Canna Comte de Bouchard (H. Cannell & Sons and Paul & Son).—The scarlet spots on the yellow ground of this variety are very fine. The flowers are large (award of merit).

Carnation Artemus (C. Blick).—A crimson flake fancy of splendid substance (award of merit).

Cattleya Mossie Empress Queen (L. Linden).—A massive flower in all respects of the most pleasing type. The sepals and petals are clear rose, while the broad fimbriated lip is white at the outside with a crimson centre. The side lobes are yellow, as is the front portion of the throat (award of merit).

Cattleya Schilleriana Hardy's variety (T. Stafford).—This may be most comprehensively described as a very much improved form of the type (first-class certificate).

Cattleya Mendeli Madonna (W. L. Lewis & Co.).—The broad sepals and petals of this beautiful form of *Mendeli* are pure white, save

for the most delicate blush suffusion. The fimbriated lip is white at the outer margins with a patch of crimson red. The throat is golden yellow (award of merit).

Cœlogyne Dayana The Dell variety (H. Ballantine).—The variety here recognised is one of decided merit. Besides the flowers being thicker set on the spike, the lip is very much finer in all respects (award of merit).

Clematis Marcel Moser (Jean Moser).—A most striking Clematis. The centre of each petal is rose, and the outer portions silvery white (award of merit).

Clematis Duchess of Albany (G. Jackman & Son).—Soft rose is the colour of this beautiful Clematis, which belongs to the hybrid coccinea section (award of merit).

Croton Her Majesty (Fisher, Son & Sibray).—A narrow straight-leaved variety, of a clear yellow colour with a green tip (award of merit).

Cypripedium Chapmani magnificum (H. J. Chapman).—This is a very handsome Cypripedium, from a cross between bellatulum and Curtisi. The round dorsal sepal is white veined and spotted with dull crimson, this also being the colour of the petals. The lip is of good shape, and deep claret in colour (first-class certificate).

Cypripedium cono-bellatulum (R. Johnson).—With a name such as this hybrid has been given there is no necessity to give the parentage, of which the evidences of both are perceptible. The ground colour of the whole flower is cream, profusely spotted with dull crimson (award of merit).

Davallia hirta (F. Sander & Co.).—This is a handsome Fern that will be accorded a high position in public favour when it becomes known. The frond is about 3 feet in length, and almost 15 inches across at the broadest part. The habit is very graceful (first-class certificate).

Ficus radicans variegata (W. Bull).—A charming plant, with well pronounced silvery variegations (award of merit).

Iris Lupina (R. Wallace & Co.).—A species growing to a height of about 10 inches. The standards are brown with silvery streaks, the falls being rather lighter in colour save for a deep velvety patch (award of merit).

Lælio-Cattleya Lady Wigan (Charlesworth & Co.).—The parents of this bigeneric hybrid are *Lælia purpurata* Russelliana and *Cattleya Mossiae aurea*. The flower is large, the lip being superb. The outer portion is white, flushed rose, the veins towards the throat being bright maroon. The throat is yellow, faintly mottled with crimson. The sepals delicate blush in colour are narrow, and the petals, which are broad, are of a slightly darker hue (first-class certificate).

Lælia purpurata fastuosa (A. Warburton).—A very fine purpurata. The sepals and petals are very rich rose in colour. The lip is of good shape, and the colour is rich crimson (award of merit).

Lælio-Cattleya tyntesfieldiense (G. W. Law-Schofield).—A very beautiful bigeneric hybrid. The sepals and petals are rose, with an indistinct buff suffusion. The superb lip is rich velvety crimson, becoming slightly paler towards the outer portion (first-class certificate).

Odontoglossum Pescatorei Imperiale (L. Linden).—A variety of striking beauty. The three sepals are white, flushed rose, and with a large central blotch of crimson brown. The ground colour of the petals is pure white, as also is the lip, the smaller spots being the same colour as the blotches on the sepals (award of merit).

Odontoglossum excellens var. (R. Ashworth).—This is a charming form of the well-known excellens that is said to be a natural hybrid (award of merit).

Odontoglossum crispum Queen Victoria (H. Low & Co.).—One of the best crispums in the exhibition. The shape is almost perfect. The rose-suffused sepals each carry a large light chocolate blotch, as do the whiter petals. The lip is white and a little fringed with yellow and brown markings (first-class certificate).

Odontoglossum sceptrum aureum (W. Stevens).—Very charming is this variety. The spike is good and well formed. The colour of the sepals is buff lightly barred with yellow. The petals are yellow with buff mottlings, while the lip is yellow with a buff central blotch (first-class certificate).

Odontoglossum excellens Thompsoni (W. Stevens).—A variety of the greatest beauty. The chocolate brown blotches on the various organs, of which the ground colour is yellow, are singularly handsome. The form of the flower leaves nothing to be desired (award of merit).

Odontoglossum crispum Annis (W. Stevens).—So far as shape is concerned this variety is very fine. The colour of the sepals and petals is white with maroon flushings, blotches, and spots. The lip is white with brown spots and a yellow crimson veined throat (award of merit).

Odontoglossum crispum Petersi (Peeters).—The flowers of this variety are rather small, but of good form. The spots and blotches are a rich chocolate brown (award of merit).

Odontoglossum crispum Starlight (King).—Perhaps the most distinct crispum in the show. The sepals are deep rose profusely spotted with brown. The shapely petals are of white, with a rose suffusion chastely spotted. The lip is white, with yellow in the throat, and sparse chocolate spots (first-class certificate).

Petunia Mrs. Fred Sander (F. Sander & Co.).—Of the richest rose colour, and with perfectly double flowers of considerable size; this is a superb acquisition. The edges of the flowers are chastely fimbriated, and greatly increase the beauty of the plant (award of merit).

Pyrethrum Wilson Barrett (Kelway & Son).—A perfectly double variety of the best shape. The colour is very bright deep rose (award of merit).

Phyllocactus Adonis (J. Veitch & Sons).—The delicacy of the rose colour of this variety is most pleasing. The flower is of good form (award of merit).

Phyllocactus Syrens (J. Veitch & Sons).—Of beautiful form; the petals in this variety are very fine. The colour is pale rose (award of merit).

Rhododendron fl.-pl. Madame Moser (J. Moser).—A semi-double form of a deep crimson colour (award of merit).

FRUIT AND VEGETABLES.

Although the show is, in the main, one of plants and flowers, yet variety is afforded by the best displays of fruit and vegetables that have yet been seen in the Temple Gardens. These, what may be termed utilitarian sections, are that and something more, for they have a beauty all their own, and prove a great source of attraction. Though in some instances fruits and vegetables were more or less mixed, in our snatch note references they will be kept together as much as possible, and briefly described in the order in which they were seen before the Judges' awards were made, a record of which will follow in due course.

FRUIT.

First to receive attention must be the striking collections of trees in pots as arranged by Messrs. T. Rivers & Son, Sawbridgeworth, and Mr. Jas. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton; and though these groups are in the chief marquee, flanked with magnificent Roses and faced by rich banks of Orchids, they maintain their power in arresting attention and inciting expressions of admiration, as well they might. In their fine exhibit it may be said that Messrs. Rivers achieve another triumph in growing Peaches and Nectarines in pots, of which they exhibit some fifty or sixty trees of various ages and shapes, but all in rude health, and cropped with handsome fruits. The Nectarines consist of the unrivalled earlies, Cardinal the first of all, and the later and larger Early Rivers, brightly coloured, and set the trees aglow. Cardinal when first shown was small, but the fruits seem to get larger yearly, the result of more experienced cultivation. It has to be remembered they have only been seen on trees in pots, or gathered from them, and it is practically certain that this precocious Nectarine from well managed planted out trees will be larger than most of the old and much later varieties usually grown in gardens. As to Early Rivers, the fruits are as large, bright, and rich as the most exacting could desire. The Peaches shown are mostly Early York and Early Rivers. A tree of Guine de Annonay Cherry, twenty years old, in a 15-inch pot, attracted much attention, as it was laden with clusters of dark red fruits. Altogether the group is a splendid one.

One of the most remarkable exhibits of its kind from a private garden—that of Leopold de Rothschild, Esq.—consists of some fifty trees in pots ranging from bearing Fig trees a foot high to Peaches, Nectarines, Plums, and Cherries seven or eight times the height, all in the best possible health, and bearing the best of crops of excellent fruit. Boxes of gathered fruit are also shown, these including Frogmore Bigarreau, Empress Eugénie, Bigarreau de Schrecken, and Frogmore Bigarreau Cherries, also ripe fruits of Cardinal and Early Rivers Nectarines, six of the last named weighing 31 ozs. A note attached states that trees started December 1st, 1896, grown in the same house, gave ripe fruits on the following dates:—Cardinal Nectarine, May 12th; Early Rivers, May 24th. Mr. James Hudson, the grower of this collection of fruit, deserves unstinted congratulations.

Passing through other marquees between long and brilliant avenues of flowers, we find repose in the last tent reached, for here are arranged most of the fruit next to be noticed. Messrs. George Bunyard & Co., Maidstone, have a splendid collection of Apples and Pears, about seventy dishes altogether, remarkably alike for size, colour, and quality at this period of the year. The fruits are backed by healthy fruitful pyramids of Peaches and Nectarines, and dwarf highly productive Figs. It is evident that this firm knows how to grow fruit, how to preserve it, and how to display it to advantage. The group contained the only Apples in the show, and these fresh and firm—a credit even to Maidstone.

Mr. J. McIndoe, gardener to Sir Joseph Pease, Bart., exhibits a truly admirable collection, including a good Pine, fine Grapes, Melons, Oranges, Peaches, Nectarines, Citrons, Figs, Cherries, Strawberries, Pears, and Tomatoes—something to be proud of, and would have won a high position at any show in the kingdom.

Mr. W. J. Empson, gardener to Mrs. Wingfield, Amptill, has arranged a highly attractive and meritorious collection of Strawberries—several plants heavily fruited in pots, while gathered fruits are arranged in association with black and white Grapes and Myrsiphyllum in the form of a large crown. A sturdy plant of Musa Cavendishi, with a heavy cluster of fruits, attracts much attention.

Messrs. Laxton Brothers have a massive bank of Strawberries in pots, including Royal Sovereign heavily fruited, also Leader, Monarch, and some unnamed seedlings. The fruits, especially of Leader, are very fine indeed.

Mr. G. Wythes, gardener to Earl Percy, Syon House, has a large and diversified assortment of excellent fruit, including large specimens of *Monstera deliciosa*, a well-ripened and fine cluster of Bananas, capital Grapes, Peaches, Nectarines, Figs, and Strawberries, also about a bushel of Melons and large Tomatoes.

Mr. C. Beckett, gardener to Sir W. G. Pearce, Bart., Chilton Lodge, Hungerford, stages a large and meritorious collection, including very good black and white Grapes, Peaches, Nectarines, Figs, Melons,

Strawberries, and Tomatoes, altogether over thirty dishes, and entirely creditable to the cultivator.

Mr. G. Featherby, Gillingham, Kent, exhibits splendid market baskets of Black Hamburg and Muscat Grapes, also very good Peaches and Nectarines, and large baskets of Strawberries came from the Swanley College.

Melon Diamond Jubilee.—A good sized, round, well netted scarlet-fleshed Melon, raised and grown by Mr. C. Herrin, Dropmore, was found to be remarkably sugary, and adjudged an award of merit—the first honoured Melon of the year.

VEGETABLES.

Certainly a great advance is to be noted here, not in the form of unwieldy specimens so much as for diversity, high quality, and effective arrangement. An enormous collection of splendid produce is displayed by Messrs. Jas. Veitch & Sons, Ltd. Peas, Beans, and Tomatoes in pots along the back, with bold groups in front of Mushrooms, Cauliflowers, Cabbages, Lettuces, Model Broccoli, Asparagus, Cucumbers, Leeks, Radishes, and Turnips, not a weak specimen to be found in the whole extensive group.

From the gardens of Mrs. Wingfield comes a remarkable display, extending over some 20 yards in length of table. At the back are Potatoes growing in boxes, with the front side glazed to show the tubers. Broad Beans in 6-inch pots, growing as healthfully and bearing as freely as the plants do in gardens in June and July. Peas, Carter's Dwarf and Daisy, bearing bountifully in 7-inch pots. In the front, arranged in bays or panels, divided by raised blocks of Cucumbers and Leeks, are practically all kinds of vegetables that could be had in use at the present time; and with the fruit (previously described) at the end of it forms a contribution such as perhaps has never been staged by a private gardener.

Messrs. Jas. Carter & Co. have arranged at the end of their great floral exhibit plants in pots of their Model Cucumber, bearing wonderful crops; Peas, tall and dwarf, in pots, margined with Green Fringed Lettuce, which makes an appropriate and attractive edging.

A creditable assortment of vegetables is displayed from the Horticultural College, Swanley, including most kinds in season, and Sutton's Al Cucumbers of quite unusual length. Mr. Frank Chapman, market gardener, Colchester, sends magnificent Asparagus, and Mr. G. Featherby, Gillingham, fine Cucumbers and French Beans. Mr. de V. F. Lebeuf, 22, Route de Sannois, Argenteuil, has broodingnagian Asparagus, but most visitors seem to prefer that near it from Castle Ashby.

Mr. J. T. Wray, gardener to the Marquis of Northampton, Castle Ashby, has a highly creditable collection of vegetables, including Celery almost ready for eating, gigantic Leeks and Broccoli, excellent Asparagus and French Beans, Turnips, Carrots, Potatoes, and various saladings, the whole displaying evidence of good cultivation.

Tomato Golden Jubilee.—Heavy clusters and fine gathered fruits of this beautiful variety, sent by Mr. Owen Thomas from the Royal Gardens, won a first-class certificate. In quality for eating raw this is excellent, the flavour being delicate and refreshing. It is also attractive in appearance by the cleanness in colour and transparency.

LIST OF AWARDS.

Gold Medals.—Messrs. James Veitch & Sons, Chelsea, for Hardy Flowers, Scrubs, Cactus, Caladiums, Streptocarpus, Vegetables, &c.; Messrs. de Rothschilds, Gunnersbury, for Fruit Trees in Pots, Myrtles, &c.; Messrs. Rivers, Sawbridgeworth, for Fruit Trees in Pots; Messrs. Fisher, Son & Sibray, Sheffield, for Hardy Plants; Mr. Geo. Mount, Canterbury, for Roses; Baron Schröder, The Dell, Staines, for Orchids. Note.—Sir Trevor Lawrence, Bart., President of the Society, would have received a gold medal had his plants been for competition.

Silver Cups.—Messrs. Wm. Paul, Waltham Cross, for Roses, Rhododendrons, &c.; Messrs. Paul & Son, for Roses, Cannas, and Alpine Plants; Messrs. Charlesworth & Co., Bradford, for Orchids; Messrs. Barr & Son, Covent Garden, for Herbaceous Plants; Messrs. Backhouse, York, for Alpine and Hardy Plants; Messrs. Wallace & Co., Colchester, for Lilies, Irises, &c.; L'Horticole Internationale, Brussels, for Orchids; Messrs. Dobbie & Co., Rothesay, for Violas, Pansies, &c.; Sir J. W. Pease, Bart., Hutton, for Fruit; Mrs. Wingfield, Amptill, Beds, for Fruit and Vegetables.

Silver-gilt Flora Medals.—Messrs. May, Edmonton, for Ferns, &c.; Messrs. Fromow, Chiswick, for Maples; Messrs. Cripps & Son, Tunbridge Wells, for Maples, &c.; Messrs. Wills & Segar, Onslow Crescent, South Kensington, for Palms, &c.; Messrs. Rumsey, Waltham Cross, for Roses; Messrs. Kelway, Langport, for Pæonies, &c.; Mrs. Phippen, Reading, for Decorations; Mr. Moyses Stevens, 146, Victoria Street, S.W., for Decorations; Mrs. W. Green, Romford, for Table Decorations; Messrs. Perkins, Coventry, for Decorations; Miss M. Foden, for Table Decorations; Sir F. Wigan, Bart., East Sheen, for Orchids; Messrs. Lewis, Southgate, for Orchids; Mr. J. Cypher, Cheltenham, for Orchids; Messrs. H. J. Jones, Lewisham, for Begonias, &c.; Mr. J. R. Box, Croydon, for Begonia; Messrs. James, Farnham Royal, for Calceolarias; Messrs. Cutbush, Highgate, Carnations; His Grace the Duke of Marlborough, Blenheim, for Carnations; Guildford Hardy Plant Nursery, for Hardy Plants; Messrs. J. Waterer, Bagshot, for Rhododendron and Maples; Messrs. Peed, Norwood, for Gloxinias and Caladiums; Earl Percy, Brentford, for Orchids and Fruit.

Silver Flora Medals.—Messrs. Jackman, Woking, Clematis, Herbaceous Flowers; Mr. B. Ladhams, Shirley, Southampton, for Hardy Flowers; F. Hardy, Esq., Tyntesfield, for Orchids; Messrs. W. Brown, Stamford, for Cut Flowers; Mr. H. O. Garford, Stoke Newington, for

Decorations; Messrs. Edwards, Sherwood, for Decorations; L. Mond, Esq., Regents Park, for Orchids; Mons. E. Pirat, Argenteuil, for Orchids; Mr. John Forbes, Hawick, N.B., for Carnations; Mr. G. Stevens, Putney, for Carnations; Mr. A. W. Young, Stevenage, for Gloxinias, &c.

Silver-gilt Banksian Medals.—Pantia Ralli, Esq., Ashted, for Caladiums; Messrs. Birkenhead, Manchester, for Ferns; Mr. W. Iceton, Putney, for Foliage Plants; Mr. G. Featherby, Gillingham, for Grapes, &c.; Marquis of Normanby, Castle Ashby, for Vegetables; Mr. J. Prewett, Hammersmith, for Table Decorations; Mr. L. H. Calcutt, for Floral Decorations; W. A. Gillett, Esq., Bishopstoke, for Orchids; Welbore Ellis, Esq., Dorking, for Orchids; W. Thompson, Esq., Stone, for Orchids; Messrs. R. Smith & Co., Worcester, for Clematis; Mr. M. Pritchard, Christchurch, for Herbaceous Plants; Messrs. Balchin & Son, Hassocks Nurseries, for New Holland Plants; Messrs. Cheal & Sons, Crawley, for Herbaceous Plants.

Silver Knightian Medals.—Mons. A. Belin, Argenteuil, for Asparagus; Mr. F. Chapman, Colchester, for Asparagus; Messrs. Laxton, Bedford, for Strawberries; the Horticultural College, Swanley, for Vegetables.

Silver Banksian Medals.—M. S. Cooke, Esq., Kingston, for Orchids; Major J. Joicey, Sunningdale, for Orchids; Mons. A. A. Peeters, Brussels, for Orchids; Messrs. R. & G. Cuthbert, Southgate, for Azaleas.

We must not close our report without paying a thoroughly deserved tribute to those who worked so indefatigably to make the Temple Show of 1897 worthy of the year of the Diamond Jubilee celebrations. Foremost amongst the workers must, of course, be placed the Rev. W. Wilks, of whose zeal everyone knows. Then there are Mr. J. Weathers, the Assistant Secretary; Mr. S. T. Wright, the Chiswick Gardens Superintendent, who in his own unobtrusive manner does a wonderful amount of work; and Mr. Humphreys, his assistant. During the afternoon T.R.H. the Princess of Wales, Duke of York, Princess Charles of Denmark, and Princess Victoria of Wales visited the Show, and Sir Trevor Lawrence, Bart., with the members of the Council, conducted the Royal party round the Show. Despite the rain, which fell heavily at intervals, there was a large attendance on Wednesday.

ROSE SHOW FIXTURES FOR 1897.

- June 7th (Monday).—Cambridge.
 „ 9th (Wednesday).—Chelmsford.
 „ 15th (Tuesday).—Ryde.
 „ 16th (Wednesday).—York.†
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 23rd (Wednesday).—Richmond, Surrey.
 „ 24th (Thursday).—Colchester.
 „ 25th (Friday).—Maidstone.
 „ 26th (Saturday).—Windsor and Dorking.
 „ 29th (Tuesday).—Canterbury, Hereford, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon, Ealing, Farnham, and Reading.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 6th (Tuesday).—Diss.
 „ 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
 „ 8th (Thursday).—Bath, Farnham, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.
 „ 10th (Saturday).—Manchester.
 „ 13th (Tuesday).—Wolverhampton.†
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 17th (Saturday).—New Brighton.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.
 „ 28th (Wednesday).—Chester.*
 „ 31st (Saturday).—Liverpool.*

* Shows lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any farther fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

IN MEMORIAM—THE REV. E. N. POCHIN.

IN the earlier days of the N.R.S., and indeed long before its birth, there were two clergymen whose names were well known in the Rose world, but whom few in the present generation can recall to memory. These were the Rev. C. P. Peach and the Rev. E. N. Pochin. The former of these passed away some years ago, and the latter, as we learn from the Leicestershire papers, died on Wednesday last at Barkby Vicarage, in Leicester. He was born in 1829, and so was in his sixty-eighth year. He was a keen rosarian, and was about as good a judge of a Rose as any man I ever met. I have been associated with him in judging, and although he was somewhat deliberate in coming to a decision I can call to mind no instance in which his decisions were wrong; indeed,

I have rarely known them to be questioned. It was always pleasant to be associated with one whose geniality of disposition and ready and sometimes caustic wit made him so pleasant a companion. He was at one time a constant exhibitor, but latterly he had withdrawn himself from all public engagements, and so we were unable to look to him to be as he was before wont to be, one of the judges at our National shows. How often when there was some doubt as to the identity of a Rose has it been said by one of the judges, "Oh, ask Pochin!" and when he had said the name it was at once recognised as correct, and we wondered how we had been so stupid as not to see it before. And so one by one the veterans are called away, and the battle is left for younger men to fight. I can only wish that amongst them may be men who can grow and know Roses as well as our deceased friend. He was also formerly a frequent contributor to the pages of the Journal, and had always words of wisdom to say to us.—D., *Deal*.

THE WEATHER IN LONDON.—The wind continued bitterly cold and parchingly dry to the end of last week. The present week has been less bright, also somewhat milder, while on Tuesday a little rain fell in some parts of London—the first since the 5th inst. It has been a trying time for gardeners, and the growth of crops and trees has been seriously retarded. Yesterday (Wednesday) light drizzling showers fell at intervals, and while these would refresh vegetation they did not seem to materially prejudice the attendance at the Temple Show; but the day is not over at the time of penning this note.

WEATHER IN THE NORTH.—The bright sunshine that has prevailed throughout the past week has been tempered by persistent east winds, and the mornings and evenings have frequently been very cold. A slight rain fell early on Tuesday morning, and the atmosphere became a little more genial, but a deal more rain would be welcomed.—B. B., *S. Perthshire*.

NATIONAL VIOLA SOCIETY.—The first meeting of the Floral Committee was held in the Reading Room at the Royal Botanic Society, Regent's Park, on Wednesday, 19th inst. Owing to the early date, and untoward season, only a few Violas were staged, the only one gaining a certificate being *Endymion*, a pale yellow, superb blooms of this variety being staged by Mr. W. Baxter, Woking.

THE QUEEN'S VISIT TO SHEFFIELD.—Although the Sheffield Chrysanthemum Society was not able to carry out its wishes and decorate a floral arch on the occasion of the Queen's visit to the City on the 21st inst., it readily responded to the invitation of the Decorative Committee to decorate the Vestry Hall in Westbar, one of the halls in which the Mayor of Sheffield, the Duke of Norfolk, was giving an entertainment to the aged poor of the City. A large number of plants and a great quantity of cut flowers were freely supplied, and displayed in the most tasteful manner. We regret this is all that can be inserted of a report which reached us on Wednesday, the morning of the Temple Show.

PRESENTATION TO MR. THOMSON, DRUMLANRIG GARDENS.—We have received the following cutting from a newspaper, the name and date of which are not given:—"On Friday last a deputation from the working staff in the Drumlarnig Gardens, composed of Messrs. William Swan, Arthur Melville, and F. Maxey, waited upon Mr. David Thomson and presented him with a handsome marble timepiece as a token of their respect and esteem, on the occasion of his retiring from active life after twenty-nine years' service in the gardens. Mr. Swan, in making the presentation, conveyed to Mr. Thomson the best wishes of all the employes under him, and expressed the hope that he might be long spared to enjoy the well-earned repose which he purposed taking in the evening of his days. Mr. Swan presented Miss Thomson also with several handsome pieces of silver plate. Mr. Thomson, in reply, expressed the pleasure with which he received for himself and his daughter the tokens of the goodwill and kindly feelings of the employes under him. They would both highly value the handsome gifts, and ever cherish the remembrance of the cordial relations subsisting between them at Drumlarnig Gardens." We think Mr. Thomson relinquishes the charge of the Gardens on the 28th inst. into the hands of Mr. D. Inglis.

GARDENING APPOINTMENT.—Mr. G. H. Ackroyd, Beningborough Hall, York, has been appointed to succeed Mr. D. Inglis as head gardener, Howick, Lesbury, R.S.O.

DEATH OF MR. J. T. GIBSON.—We are informed that this late well-known London park superintendent died at Hackney on the 17th inst. The deceased was son of the late Mr. Gibson, who transformed a swamp at Battersea into one of the most beautiful of the London parks. Mr. J. T. Gibson was in turn Superintendent of Hyde Park, Regent's Park, and Victoria Park, retiring from the last named park through ill health about three and a half years ago on a pension allowed by the London County Council. Mr. Gibson was in his fifty-sixth year, and his remains were interred at Shenfield on Saturday last.

SHIRLEY GARDENERS' ASSOCIATION.—The monthly meeting of the above Society was held at the Parish Room, Shirley, Southampton, on the 17th inst., the President, W. F. G. Spranger, Esq., conducting the meeting. There was an excellent attendance of the members. The evening was devoted to a "microscopical demonstration" of botanical and entomological subjects. There were about twenty instruments, the whole arrangements being conducted by A. C. Rogers, Esq., Red Lodge Nursery, Bassett, who opened the proceedings by giving a brief address on the practical value of the microscope to the horticulturist and others, enabling them to trace, as in a slide containing a portion of coal which he was showing, the exact nature of the substance under observation. He advised all those who could to obtain an instrument, if only for pleasure, as he felt sure its use would charm the senses and delight the eyes of its possessor. The company then went the round of the microscopes, the subjects on view being constantly changed and described by those in attendance. A vote of thanks to the demonstrators was very heartily given.

WAKEFIELD PAXTON SOCIETY.—On Saturday afternoon 15th inst. a party of about twenty-five members of the Paxton Society (including a few ladies), paid a visit to the residence and grounds of Dr. Clark, Professor of Horticulture, Yorkshire College, Leeds, at Laurel Bank, Headingley, and inspected his large and magnificent collection of Tulips, which were greatly admired. The Professor clearly and fully explained to his Wakefield friends his experiments in growing and propagating Dutch and florists' Tulips, and imparted much interesting and valuable information. The visitors were entertained to tea on the lawn, and took back with them to Wakefield a large collection of Dr. Clark's specimen Tulips. These were admirably arranged on the tables at the Society's headquarters the same evening, and when the members assembled at the usual weekly meeting, the blooms were inspected with interest. Mr. W. H. Milnes presided, and Mr. B. Whiteley occupied the vice-chair. At the request of the Committee, Mr. Whiteley had, after the return of the party from Leeds, prepared a paper giving an interesting account of the visit to Dr. Clark's grounds, and detailing what the visitors saw and heard there. Mr. Whiteley said the professor's residence and grounds were prettily situated in the pleasantest suburb of Leeds. The grounds, which were 4½ acres in extent, were connected with the Professor's residence, which he has occupied for about six years. The grounds were on the slope of a well-wooded valley, and just now the foliage of the trees looked very fresh and healthy. One portion of the grounds was only annexed last year, and during the winter it was trenched 2 feet deep, and had recently been planted with 528 varieties of Gladioli, new sorts of Strawberries, a collection of Ruby Gem Wallflowers, and young and dwarf fruit trees. There was an Orchid house in the grounds containing some rare and valuable varieties. The chief and great attraction was an immense and magnificent collection—numbering upwards of a million—Dutch and florists' Tulips in no less than 700 varieties. Although the florist Tulips have not yet reached the blooming period, and notwithstanding that four recent hailstorms had destroyed many of the other blooms, there was a very large and most charming display of Tulips; some of the flowers being about 8 inches across. The various tints and shades were so arranged as to produce a striking effect, and looking down the long and sloping beds, and across the valley, the visitors gazed upon a sight which well repaid them for their journey, and reminded some of the party of their visits to the bulb farms in Holland. The Professor distinctly gave his visitors to understand his grounds were not a show garden, but were employed for experimental purposes, and it was evident from what he told the Paxtonians during their two hours' stay at Laurel Bank, that he has achieved great and important results since he began his experimental gardening there. Several floral novelties and wonderful "breaks" were pointed out to such experienced growers of florists' Tulips as Mr. A. Moorhouse and Mr. W. Calvert.

SUCCESS WITH ORCHIDS.

I ENCLOSE you a few Orchid blooms for your inspection. The forms of *Dendrobium nobile* are very interesting. You will observe that No. 2 has a complete absence of curl in the lip, which makes it very distinct. No. 3 is also distinct, being much more white than the original variety of *D. nobile*. No. 1 approaches the variety of *nobile nobilius*. The *Cypripedium villosum* is also of good colour. I should be glad if you would give me the name of the *Cattleya*. Is it a pale form of *Trianae*? I should like to say that these Orchids cost 1d. each two years ago, a box of sixty costing 5s.—W. J. GRACE, *Bickton Gardens, Fordingbridge*.

[The Orchids were very attractive. The results you have achieved are highly creditable, and must be very gratifying to you. Each variety is good. The *Cattleya* is a pale form of *Mossiae*. You have evidently made the best of a good bargain, and we trust your plants will still continue to make excellent progress.]

MANCHESTER AND NORTH OF ENGLAND ORCHID SOCIETY.

In their circular first sent out the suggestors of the above Society state that it is estimated that within a radius of thirty miles of Manchester the Orchid wealth of the country is centralised, and at the instance of several gentlemen in the district it was thought advisable to form a Committee, with head-quarters in Manchester, composed of amateur or private growers as separate and apart from the Orchid Committee of the R.H.S. Subsequent meetings were held, and the Society was formed. The Society is founded for the purpose of fostering and encouraging the growth and cultivation of Orchidaceous plants generally. (a) By the awarding of F.C.C., A.M., and cultural certificates, and by awarding prizes for Orchids in money or such other form as the Committee may determine, sums being voted from the Society's funds. The entrance fee is one guinea, and one guinea the annual subscription. The voting is by ballot. In rule 12 the Committee state that they shall cause a flower from every plant receiving a F.C.C. to be painted by an artist to be appointed by them at the expense of the person owning the plant, and such painting shall be the property of the Society, and shall be kept by the Hon. Sec. in a suitable and secure place for purposes of reference. The first meeting was held in the Coal Exchange on Thursday last, a room with excellent acoustic properties, and other meetings are to be held fortnightly, so as not to clash with those of the Royal Horticultural Society.

Considering that this was the first meeting the exhibits were more numerous than one would have expected, and the enthusiasm displayed by many of the Manchester gentlemen present augured well for its success as a permanent and lasting good to all Orchid lovers in the North. Private growers made an admirable display, foremost being Mr. Lofthouse, gardener to A. Warburton, Esq., Vine House, Haslingden, who had grand and well-flowered forms of *Laelias purpurata* and *purpurata Schröderae*; *Cattleyas Mossiae* and *Mendeli*, very fine; *Oncidium Marshallianum*, *Brassia maculata*, *Dendrobium Jamesianum*, and excellent *Odontoglossum crispum*, amongst which was a giant form, quite the largest we have seen.

Mr. Alexander Hay, gardener to R. Shorland Ball, Esq., Wilmslow, had a handsome collection in choice variety, every plant being well grown and finely flowered. Conspicuous were *Cypripedium Schröderae splendens*, *Odontoglossum vexillarium*, *Dendrobiums Jamesianum* and *Dearei*, *Cattleyas Mossiae* and *Schröderae*, a well-cultivated *Cattleya Skinneri*, and *Masdevallia Veitchi*. Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs., was noted as usual for varieties of the highest quality, and had a deserving honour conferred upon him by gaining five certificates out of six exhibits.

R. Ashworth, Esq., The Ashlands, Newchurch, had *Cattleya Mossiae*, *Cypripedium Rothschildianum*, and *Cattleya Mendeli vestalis*. G. W. Law-Schofield, Esq., New Hall, Rawtenstall, had a fine and well-flowered plant of *Cattleya Skinneri superba*, also *Laelia purpurata* and *Cattleya Mossiae*. Duncan Gilmour, Esq., Sandgate, Sheffield, had an attractive collection, comprising *Cattleyas*, *Odontoglossums*, and *Dendrobiums*—small plants, but nicely flowered.

Interesting, too, were those set up by Mr. Spurr, gardener to H. Greenwood, Esq., Highfield, Haslingden, amongst which was a noticeable plant of *Anguloa Clowesi* with deep lemon-coloured blooms. Mr. Shiner, gardener to E. J. Sidebotham, Esq., exhi-

bited *Dendrobium Jamesianum* profusely flowered. Messrs. Jno. Cowan & Co., Ltd., The Vineyard, Garston, exhibited a large and diversified table of Orchids in bloom, including some excellent types of *Laelia purpurata*, both light and dark varieties, *Cattleyas Mossiae*, *Dendrobiums clavatum*, *Dalhousianum*, *Devonianum*, and *crepidatum roseum*, with *Laelia flava*, altogether a splendid contribution.

The Committee sat from twelve to one, and in that time had granted the following awards—viz., first-class certificates to W. Thompson, Esq., Stone, for *Odontoglossum crispum Annie*, a magnificent long-spiked rose variety, heavily blotched with crimson; *Odontoglossum excellens Thompsonianum*, with pale yellow ground, having sepals and petals banded chestnut brown; *Odontoglossum aureum sceptum*, a variety in light and rich shades of yellow; *Cattleya intermedia alba*, perfect and greatly admired; and *Cypripedium Rothschildianum giganteum*. R. Shorland Ball, Esq., for a handsome *Lycaste Skinneri alba*, well flowered; for the rare *Cypripedium callosum Sanderæ*, and an award of merit for *Cattleya Skinneri alba*. G. W. Law-Schofield, Esq., secured awards of merit for *Cattleyas Skinneri oculata*, also for a fine bloom labelled *C. Gaskelliana alba*, but which partook more of a *Mossiae* type than the true *Gaskelliana alba*. Of course there are a few matters that will be righted as the Society progresses, but a good beginning has been made, and in Mr. Shorland Ball, the Hon. Treasurer, and Mr. Gent, the courteous and willing Hon. Secretary, the Committee have two gentlemen who will do all in their power to keep the Society up to a very high standard.

CERASUS VIRGINIANA.

SOME years ago there was a tree growing in one of the belts on the south boundary of the old Chiswick Garden which attracted the attention of lovers of trees when it was in bloom, and which was erroneously labelled *Cerasus capollin*. That it was not *Cerasus capollin* was evident from the broad ovate lanceolate leaves and the bold erect leafless racemes of flowers. It was a tree which engaged Loudon's notice, and in the "Arboretum et Fruticetum Britannicum" he remarks, when treating of *Cerasus capollin*, that the flowers produced on a plant bearing this name in the London Horticultural Society's Garden are not those of that species. "Its leaves also are much too broad and elliptical; and the leaves, the flowers, and the whole tree bear so much resemblance to *C. virginiana* that we have no doubt of its being only a variety of that species, but of larger and more luxuriant growth."

Of the tree thus referred to a representation is given; at the same time we do not consider it the *Cerasus virginiana* of Michaux, neither is it the *Cerasus Padus* of Decandolle as some have supposed it to be. After a careful examination we have come to the conclusion that it is the true *Prunus virginiana* of Linnæus, and the *Prunus Cerasus rubra* of the "Hortus Kewensis," ed. 1. It differs from *Cerasus Padus* in the habit of the tree, which is stronger and more rigid and luxuriant; in the glandular leaves, those of *C. Padus* being eglandular; in the long, rigid, erect, leafless racemes, those of *Padus* being drooping and leafy; and by its later flowering, which is not till the middle of June. It is a tree of great beauty which appears to be very little known. The spray represented was grown in the garden of the late D. Hogg.

[This will be of use to others besides "Devonian," page 469.]

WEDDING BOUQUETS.

FLORISTS of all descriptions have been extremely busy this season, and seem now to be entering upon an era of still greater activity. Having to be "up to date" in all matters connected with floral decorations, I recently took the opportunity of conversing at some length with one of the leading Court florists as to the style of decorations in vogue for the present season. Among other things bouquets were touched upon, and it seems that there are no startling differences in the style of them this year, with the exception of orders executed for a few individuals who may be termed faddists, whose ideas do not take with the general public.

Shower bouquets are as popular as ever, and whoever hit upon this bright idea seems to have grasped one which has come to stay, for when well made this style of bouquet is one which will be very hard indeed to surpass. The round and conical bouquets are still much liked, and a very noted Court florist still executes the majority of his orders in this style, varying the size of them, and at times having a few strings of flowers depending from them. Favourite flowers for making bridal bouquets are Lily of the Valley, Gardenias, white Orchids, Freesias, White Carnations,

Stephanotis, with a little Myrtle, Orange blossom, and Asparagus plumosus nanus intermixed. Malmaison Carnations are in great demand for bridesmaids, and so are yellow, pink, and red Roses, Ixias, Plumbagos, and Marguerite Carnations. Trails of Asparagus deflexus are also largely used for hanging from the bouquets, with a few flowers wired to them.

Making a bouquet seems to some persons a formidable task, but like all work connected with floral decorations it becomes simple enough with practice, provided the operator has a fair amount of taste and liking for the work. All flowers used for the purpose should be wired, and it is by doing this in a suitable way that the road to success is found. The style of flowers used varies considerably, and each must be treated in a way suited to its peculiarities.

Let us take, for instance, Lily of the Valley. Every flower of these ought to be wired with thin wire the whole length of the stalk, twisting the wire deftly between the bells. Roses require stouter wire to be passed through the calyx, and, in the case of those almost full blown, through the base of the petals. Eucharis should have a thin wire pushed through the tube of the flower just under the cup, a little cotton wool may then be wrapped round the tube, and the flower be mounted on a stiff wire. Gardenias and Carnations need one or two fairly strong wires to be pushed through the calyx, the ends being then twisted together. Orange blossom and Stephanotis should have every pip wired. Many Orchids require very careful handling to prevent injury, and in the case of such a little cotton wool should be placed around the stem or tube of the flower before the wire is twisted around it.

When the whole of the flowers and a good amount of Asparagus has been wired some should be mounted on longer wires, and others made up into little loose bunches with some greenery intermixed. To illustrate my meaning, let us suppose that a bouquet is to be made entirely of Lilies of the Valley. If three or four spikes are wired together, a leaf added, and the flowers then arranged in position by bending the wires slightly so that they stand almost clear of each other, it is easy to comprehend that a number of these little bunches fastened together could be made to form a bouquet of almost any required shape. Now let us suppose that Gardenias and Lilies are to be used in combination. The former must then be used as a groundwork, with spikes of the latter standing well up above them here and there, a few leaves

of Asparagus plumosus nanus being also mixed in as the work proceeds. These two illustrations will, I think, serve to show the manner of dealing with flowers of various types; the principle is to use the heavy ones for groundwork, with sprays of spiky flowers rising above them.

In making bouquets an important point to remember is that the weight should be kept as low as possible, therefore no more material ought to be used than is absolutely necessary. For very large ones it is sometimes necessary to use a central stick, but for those of moderate size it may be dispensed with. At the start I usually bind up a neat bunch to form the centre; the stems

of these flowers being strongly wired gives a firm foundation to work upon. For binding I prefer string to wire, as it seems to hold the flowers in position better, and by giving it a half hitch occasionally there is no fear of slipping. As each ring of flowers is added a little moss should be worked around the stem of the bouquet, to enable the operator to fasten them in the exact position required; but as little as possible ought to be used, as it adds so greatly to the weight.

If any difficulty is experienced in fixing the flowers exactly as required, a few sprigs of Box may be wired and worked in between the stems of the flowers, the points of the Box, of course, being underneath the flowers. As the bouquet increases in circumference longer and stronger wires must be used for mounting, and if several small bunches are fastened to one main stem the handle can be kept quite small enough to draw through the bouquet paper with ease. Before

this is fastened on a fringe of the Asparagus should be placed around the flowers, allowing it to project far enough to almost hide the paper when placed in position. Shoots of Myrtle must always be intermixed with a bridal bouquet, and these ought to rise well above the flowers. The addition of a wickerwork or paper holder, with a few ribbons to match the colour of the flowers, completes the arrangement. The holder must be secured to the paper with strong pins, made expressly for the purpose.

In making a shower bouquet a somewhat different form of procedure has to be pursued. The body of it in this case may be either round, rather flat, or conical, as taste may dictate, and when this part is made up the "showers" should be constructed separately. They are formed on the same principle as long slender shoulder sprays, starting from a very thin point; the shower gradually widens as it increases in length, and may be from 3 to

FIG. 91.—CERASUS VIRGINIANA.

4 inches in width at its widest part—i.e., where it is to form a junction with the body of the bouquet. These showers should be finished off with a strong stem, and then tied to the body of the bouquet, in the front of it; the back will thus be rather high and straight, so that the showers appear to fall from the hand or down when the bouquet is carried. Special papers are made for bouquets of this style.

A modification of the shower bouquet, which is now much used, is of the old round form, with two or three strings of flowers depending from it. The flowers forming these strings are simply wired together in little bunches, and the ends of the wires cut off level with a strong pair of scissors; each little bunch is then held between the fingers in an horizontal position, and a strong green wire bound around the centre of the wire stems. I think the matter will appear quite clear to anyone when I say that when completed and fastened to the bouquet they represent little sheaves of flowers dangling on a string from it. Bridesmaids' bouquets are usually much smaller than those of the bride, and may be made of flowers of any colour, but only one colour should, as a rule, be used for each.—H. D.

NOTES FROM IRELAND.

SELDOM, probably, has the season now with us been fraught with more anxiety or beset by so many petty vexations to those who, as farmers or gardeners, look to the land for its manifold gifts to reward their labour and care. At present an active endeavour to overtake long-deferred arrears of work shelves for the time any analysis of prospective results, and even those who can pause and consider the question could neither venture to build any great hopes on present appearances nor find sufficient ground for despair.

One cursory glance over the past ten months, independent of weather statistics, leaves the vague impression that it has been one long wet period; a broken summer following the abnormal drought prevailing until July, 1896, was well in, then a dripping autumn, followed by a winter of many weathers highly diluted with water, and the wet spring up till recently has kept the land saturated, prohibiting to a great extent the normal work of preparation. This at least is the case in heavy retentive soils of the limestone district, and now, in the middle of May, Potato planting is yet in operation.

My friend the busy man is not, so far as farming operations are concerned, complaining at present, although he grumbled both loud and deep during the weary waiting previously. There is, indeed, no time for lamentation with carts going in one direction, brakes, harrow, and roller in another, whilst ever and anon the rooks go screaming off one corner of the farm at the smell of his powder to drop silently into the other. It is a stirring time truly; even the steady farm horses as they come up between the long lines of field Peas seem to catch the spirit of activity, and require a good deal of managing by the driver to tack them on the headland as he breaks between the drills or moulds them up. The effects of this stirring are quickly seen in the colour and growth of the plant. On a warm southern slope nearer to Dublin we saw several acres of Dickson's First and Best in bloom on May 10th. This variety finds favour in leading for market purposes, and William I. comes second.

Another important crop is Strawberries, of which it is as yet premature to speak, but the busy man thinks highly of Royal Sovereign for forcing; there is, in fact, sovereigns in it, and those I saw with him were very handsome. Catering for the market is a fairly good test of general utility. How well the Wheat looks; it was lately harrowed and rolled, looking very miserable after the operation for a couple of days, yet it is wonderful what the stirring did for it; it is now grand, in spite of chilling east winds and frosty nights. Frosty nights in May, and nothing growing except the Wheat. Such has been the case up to the 15th; vegetation generally seemed arrested, yet there is no great evidence of damage so far. Forest trees clad in tender shimmering green, the earliest of which to dress appeared to stop midway in the operation, and the latest, such as the Oak and Ash, now clothing themselves simultaneously, make spring appear for the nonce universal in its garbing.

Frosty nights and the fruit? There is no tale of woe at present. Cold, sunless days up till recently were, perhaps, under the circumstances, the kindest things we could have. There should be a little fortune in spring Cabbage now, but our expert growers have found difficulties in this direction as well as with Broccoli; a complaint which has, apparently, been general. Such things, possibly, enjoy a season of rest at the decline of the year after being established, such as is afforded by dry weather, and failing this attenuated rather than consolidated growth leads to bolting in the Cabbage tribe and all sorts of vagaries among the Broccoli.

Glorious are and have been St. Brigid's Anemones in the borders, giving welcome tones of colour amongst almost overpowering masses of golden Doronicums. One should, however, hardly tire of what has been the most useful of hardy flowers for cutting, improving after being twenty-four hours in water. Every year we like to strike a note of admiration by sounding the praises of Tulipa Gesneriana; it stands so well when cut, and makes a fine decorative object in bowls of wet sand. All our Daffodils this year were gathered in the bud stage to open in a temperate house ere used for furnishing. Their lasting properties appear to be enhanced by the process, the ends of the stalks being again cut before placing in the vases. Some beautiful boxes of N. Emperor came direct by parcels post from Scilly, but their keeping qualities were unfortunately limited to a few hours after the journey. From one of our chief Dublin florists were received superb samples of a giant single Violet. They were at the time thought to be "California," but after noting expressions of opinion upon that variety, with the unqualified praise given to Princesse de Galles, doubt has arisen; anyway, the blooms alluded to resembled a highly glorified Czar.

On the lawn a huge Snowy Mespilus developed all its charms; it was, indeed, a thing of beauty. How bare the old Castle looked after its annual cropping of the Ivy! But it is the right thing to do, and was done at the right time—just as life was stirring in the old stems, and tender fresh foliage is now springing out from base to turret. We noted, in driving through the Phoenix Park, how bright the "People's Gardens" looked with spring flowers *en masse*; particularly gay were the Tulips. One is pleased to see additional character developing in this noble park, as evidenced by a broad, bold planting of Cupressus macrocarpa, securely fenced in from the deer. The venerable Thorns are somewhat late in blooming, for the Park lays high, and is swept by chilling winds. Through March and April many a bright patch of Anemone fulgens brightened the small holdings on the sunny banks overhanging the Liffey. On these dry slopes early Strawberries and early Peas revel in a copious rainfall, and the acute angle facing due south is a veritable sun trap, when there is any sun to be trapped. What a field, too, for Daffodil culture if these small cultivators could be stirred up to grow some of the more popular varieties!

In traversing this picturesque valley of the Liffey an unsatisfactory feeling obtains that retrogression is the order of the day. So many spots where "once a garden smiled" are now scratched by hens or browsed by goats. One cannot but think that many stray sixpences would be left here by the thousands of city folk, who come on "pleasure bent," in exchange for posies or roots, or fresh-gathered fruit. Any inquiry on this head is met with the ready response, "It doesn't pay;" but the answer is unsatisfactory, especially in noting the high price paid in Dublin for travel-stained goods of this description, the bulk of our city toilers regarding such things as luxuries beyond their reach. It is so, but it should not be so.—K.

TOMATOES FLAGGING.

ON page 430 of last week's *Journal* Mr. H. Pearl, after speaking of the dreadful flagging in his Tomato plants, asks Messrs. Abbey and Dyke "What is the cause, and what can be done in the dilemma?" The cause of the flagging, drooping, sleeping, or collapse in Tomato plants is a subject which has been so fully dealt with and described in the pages of the *Journal of Horticulture* that I should have thought by this time every Tomato grower would have been perfectly familiar with its cause. To refresh your correspondent's memory, however, I may say that the flagging is no doubt caused by the growth of a minute fungus (*Fusarium Lycopersici*) in the roots and stem of his Tomato plant. I know only too well the feeling of your correspondent, for I have experienced the same myself, and, therefore, realise how very disheartening it is to see what appears to be perfectly healthy plants to-day flagging and dying the next.

The fungus causing the flagging disease in Tomatoes grows from spores which are present either in the soil in which the plants are growing or in the seeds themselves. When the spores are in the soil they germinate and produce a very tiny thread-like body (hyphæ), which on coming in contact with a Tomato root is able to penetrate through the outer layer of cells into the vascular tissue. If a flagging plant is taken from the ground and the stem split or cut in a longitudinal direction, a certain portion of it will be brown in colour. This brown portion—if the plant is taken up as soon as it commences to flag—is the vascular tissue, and is the part of the stem where the chief supply of water or crude sap passes from the roots into the leaves. When by the presence of the fungus the cells of the vascular tissue are disorganised they cannot perform their proper functions, the supply of water is cut off from the leaves and stem, and the plant flags and dies. When the spores of the fungus are in the seeds they germinate and develop at the same time as the plant, ultimately producing its death.

What can be done in the dilemma? This is a question I have for

a long time been trying to solve, but so far I have not yet succeeded in doing so. I know that as a remedy 1, 2, and 4 bushels of lime have been recommended, but this has been tried and found wanting. Kainit and basic slag have also been recommended, but these substances have been tried with no better result; for this year I applied to the soil in my Tomato houses 1 lb. of kainit and 2 lbs. of basic slag per square yard, well mixing with the soil before planting, but still some of my plants are dying with sleepy disease. I would strongly recommend your correspondent to read what Mr. Iggulden says about this disease on page 175, for there he will see that the above writer has found water his best remedy, and I can partly endorse that statement. Owing to pressure of time I must now leave the subject, but I will return again to it in the near future.—W. DYKE.

INSECT INVASION.

WITH eyes that are ever on the watch, the presence of the earlier aphides, at any rate in our houses, may be detected and stamped out. Thrips, too, may be detected, and the remedy for the aphid is equally death to the enemy. But there is a smaller pest which does an infinity of mischief, and is not so quickly discovered. In the houses this, since I have used the vaporiser, I have found far more troublesome than aphides—I mean red spider. I dread the insignificant little wretch far more than the aphid, and for this reason, that in all probability you never see him until you notice his handiwork, and then he is in full possession.

There are certain conditions that favour this pest, the most important being a hot dry atmosphere. Amateurs like to have their greenhouses dry underfoot; a sloppy moist floor does not give a pleasant footing to friends, and this kind of house red spider enjoys. Nurserymen, I fancy, suffer from this plague far less in proportion than we amateurs do, the secret of their success being the thorough soaking the houses get at night and morning, making a moist atmosphere almost perpetual, which our little enemy dislikes. To keep the rascal in check, this thorough soaking is a great assistance. Sulphur on the hot-water pipes also disagrees with the mites, but then this needs most careful handling by the tyro, and who, while he may settle his enemy, may also settle many a plant that the spider had not touched.

I once had a Peach tree three or four years old covered with a glass roof, the end of which was perfectly open. I found the tree badly attacked by red spider. The stem of this tree was 2 inches in diameter and 6 feet high, so that the branches running on wires under the glass were at least 8 feet off. I thought I would quickly rout the intruder, and placed two or three small patches, not larger than a shilling, of flowers of sulphur on the ground, and lighted these, the end of the place remaining open. What the spider thought of I cannot say, but the tree simply gave the battle up and died at once. If this happened under glass that had plenty of vent, with one end completely open, it is easy to see how excessively careful one need to be in employing such a remedy with closed doors and windows.

Latterly I have tried the suggestion of our friend Mr. W. Taylor, and when I use the XL vaporiser I add to the liquid a half teaspoonful (I am feeling the way) of sulphurous acid—mark it is sulphurous acid, not sulphuric, which is what a person hesitating about the name would be almost certain to have given him if at a chemist's. On some plant that I do not care about losing I mean to try a diluted acid, spraying it. Certain plants seem to favour the advent of red spider. Setting aside Melons and Cucumbers and the Vines, I have found Fuchsias, Salvia Halleri, Tuberoses, Bouvardias (badly), Tecoma Smithi, Roses, and Abutilons invite the pest; this, at least, is my experience.

But how many amateurs know red spider? I have seen the scarlet spider often seen on plants out of doors, about the size of two fat green flies rolled into one, called red spider—well, red he certainly is, but this is not the enemy I am now speaking of. I know some people who can see red spider on a leaf with the naked eye; I might have been able to do so in days long since gone by, but not now. However, I always have my magnifying glass in my pocket, and submit a doubtful leaf to the strictest scrutiny by its aid. So far as I have seen, and I have seen many more than I wanted, comparatively few of these gentry merit the adjective red; most of them are yellowish, and the larger may have a darker spot on each side of the body; they are mostly on the under part of the leaf. If the plant is much infected, and in the angles formed by the stem of the leaf something like a web may be seen, I think the case very bad. Sometimes no spider is visible, but over the under surface of the leaf are a number of, as it were, microscopic drops of water, little shining greenish pearls. Are these the eggs? I think they are, for at times I seem to have caught the moment of hatching, and have seen the pearly drop still glistening, but now furnished with legs.

No plant can be long healthy that red spider inhabits. Its leaves lose their green colour, look sickly, and are thickly spotted with very small white spots. Those who have once seen and marked such a leaf would easily recognise it, and without searching for the pest give a verdict of red spider. If the plant be in bloom you cannot syringe all blooming plants without injuring the flowers; but it may pay to syringe them night and morning, for with red spider in abundance the bloom cannot be good. The pest is so diminutive that I do not know of any other insect that thinks it worth while to feed on it. I wish there were many.—Y. B. A. Z.

YOUR sprightly correspondent, who arranges his alphabeticals in such a fanciful way, "Y. B. A. Z." (page 437), cannot understand

"if the pest be aphides what can be done as a preventive." Well, if the aphides are already there the "preventive" stage is obviously past. It would then be a case of destruction, not simply of prevention, and I have always found it better to prevent than destroy even insect life—easier, cheaper, and more merciful.

It has fallen to my lot to have been nearly killed myself in trying to kill hordes of insects which had been allowed, if not encouraged, to swarm on plants and trees under glass. I was in a subordinate position then. If the same sad experience of being nearly killed in the work of butchery should recur now I should say it would serve me right. It would be the penalty of neglect, lack of observation and promptitude in action; or of mistakes in management or errors in cultivation.

Our friend seems very well able to kill aphides, also, no doubt, other insect pests; and he gives good, but not the best, advice when he says "The presence of a few pests should be the signal for immediate fumigation, or, as he seems to prefer, vapourisation." I have not had occasion to try the punishing power of the last-named operation on aphides, as they have been easily enough mastered in the old way, and with the old means—i.e., prevented; and if instead of waiting till he could see even a "few insects" (and fail to see ten times more that would probably be not far distant) he had fumigated or vapourated before they were there, he would then perhaps not be able to see any insects at all, because there would be none. If he were to pursue the practice of light periodical fumigation when his plants or trees were thoroughly healthy and clean he would find a saving in material, and need not give himself the least trouble about cooking "aphid eggs," because without a "few aphides" he would have no eggs to cook.

The ruminations of "Y. B. A. Z." on turning plants out of greenhouses at this time of the year for scrubbing and cleaning to rid us of green, brown, blue, and black aphids are beside the mark. The insects need not be there, and would not be there if a man have the means at hand to prevent them; and if our alphabetical friend were a gardener, as presumably he is not, as he tells us he is "an ignoramus" (which is not quite the way of gardeners), and moreover if he were my gardener and reared such a varied assortment of aphides on my plants as he enumerates, I should be apt to think the best way of dealing with them would be by getting rid of him.

Some persons appear to be in their glory among insects, which they seem to tend so lovingly and write about so entertainingly prior to the slaughter—if they ever do slay them—that I should not be very much surprised to hear of some of them sending samples for the Editor to grow in his garden, and then make experiments in killing them. I am not made in that way, but prefer growing plants, Peaches, and Grapes without an insect on them. This is actually the case with many at the present moment, and will be throughout the season, the direct result of taking action before any insects appear. Perhaps "Y. B. A. Z." will now better understand the theory and practice of prevention.—W.

[We know our correspondent as an experienced gardener, but did not know he was a prophet also. It is a fact that someone has sent us a box containing thousands of active mites, known as red spider—a veritable swarm, quickly thrown in the fire, and if there were a letter in the box it went there too. We had seen quite enough, without searching for more.]

THE MELON AND ITS CULTURE.

THE Melon is the richest and most highly flavoured of all the fleshy fruits. It is often said to be a native of the central parts of Asia and of Jamaica, and to have been first brought into Europe from Persia; but the date of its first culture is so remote that there is no certain knowledge on the subject. The Melons of Persia have long borne a high character. In 1824 Mr. Willock, Ambassador to the Persian Court, sent a parcel of seed, and another parcel in the spring of 1826. An account of ten varieties of these Melons was read before the Horticultural Society in September 1826, and the individual fruits referred to were the produce of the Society's garden that season.

In reference to present day culture, experience teaches that for producing abundant supplies of this luscious fruit in succession from early summer till late autumn, we must have the aid of light and well-heated houses. It is not my intention to treat on frame culture. These houses are of various styles—lean-to, span-roof, three-quarter span, and hip-roofed. I have seen excellent crops obtained in houses built on each of these principles; though the house which produced ripe fruit in the least time was an old flattish-roofed lean-to, sunk some 3 or 4 feet into the ground, with sliding ventilators in the back and front walls, with an ample supply of 4-inch piping attached to a powerful boiler. The gardener formerly in charge of this house as a rule cut fruit by the 10th of May, say about eight to ten weeks from planting, from seed sown about the 1st of January. A high, moist, genial temperature could always be maintained in this house with comparatively little trouble.

RAISING SEEDLINGS.—Various methods are adopted for raising plants. Some persons sow the seeds in square blocks of turf, but this practice is not recommended, because the tender rootlets are very liable to injury by the hot sun when they protrude through the sides of the turf. Others sow several seeds in a pot, afterwards potting the plants singly. But I think the best and most reliable method is to place one seed in a 3-inch pot half filled with loam, over a crock or a bit of rough material for drainage; this applies to the earliest plants raised in January or February. In the case of later plants with quicker growth and an increase of sunshine the soil dries more rapidly, then rough turf alone suffices for drainage.

If seed be saved at home and therefore plentiful, three seeds may be sown in a pot, and if they all germinate, reduce the plants to one, retaining the strongest; as soon as the plants are large enough, top-dress with loam pressed firmly into the pot, and to each plant affix a small stake. Care must be taken, as in potting all plants, that sufficient space be left to hold water enough to percolate through the whole mass of soil. Many growers recommend plunging the seed pots in a hotbed. This, without doubt, hastens germination and root action, though the plants may not be quite so strong and sturdy as they would be without this aid. We rarely plunge them for fear of cockroaches and woodlice, but place them on a shelf in the Pine stove, and generally cover each pot with a small piece of glass and shade with a newspaper. This is removed as soon as the plants appear, but shading is applied when necessary. As the small pots become fairly filled with roots, the plants may be transferred to 5 or 6-inch pots, which must in all cases be perfectly clean and dry. Use good fibrous loam, pot firmly, and assign the plants a light position, shading as required until they are able to stand the force of the sun. This applies also after they are planted in their permanent quarters. The plants must never be allowed to suffer through drought.

We will leave these plants to grow apace whilst we consider the preparation of the bed, where they will eventually be planted. In days gone by, and even at the present time, beds were and are to my mind very much larger than the needs of the plants require, whereby a far greater amount of risk to canker is run and much greater care needed in the application of water than where the roots are more restricted, although the watering of Melons is an important item at all times in their successful culture. Bottom heat is, without doubt, of great benefit where fruit is required very early.

I will now endeavour to describe our Melon beds, which are boxes and troughs—some made of wood, others of portable slates. For many years Melons have been grown successfully at Grimston in slate boxes or troughs, placed about a foot above the hot-water pipes, in what were span-roofed Pine stoves. They have lately been removed to another house, where instead of the pipes being under them they run close along the back. These boxes are 6 feet long, 1 foot 8 inches deep, and about 2 feet wide, sides and ends removable. The crops produced from these boxes have invariably been good. The boxes are always heavily drained. We also grow Melons in a wooden box, 16 inches deep and 18 inches wide, with capital results.

Our second crop last year, which ripened about the middle of June, was grown between three 11-inch boards, 3 inches extra being allowed in depth for drainage, which was composed of moderate sized clinkers, so that the average depth of soil was about 8 inches. As evidence that the results were of the first order, well-known gardeners stated they had never witnessed an equally good example of Melon culture before.

Under this circumscribed root-space system a much richer compost may be employed, and a very careful eye is needed to the watering. This is the point which pleases me—namely, when the fruit is swelling, watering and feeding can be given more freely without fear of canker. Another experiment was tried in 1894, both with regard to depth of bed and mode of training. (I will allude to the training later). The bed was made in a well-drained box, which measured 4 feet 6 inches in length, 2 feet 4 inches in width, and contained two barrowloads of compost. In this we placed two plants of Beauty of Sion, which ripened eighteen handsome fruits, weighing 36 lbs. This is not a large variety. In 1895 we put in two plants of a variety of our own raising, which produced thirteen fruits, weighing 60 lbs., the heaviest fruit turning the scales at 6½ lbs. We call it Grimston Hybrid. It is a white-fleshed Melon of good quality, very juicy, and of robust habit. I think these instances prove that Melons can be grown in a small space, and without the aid of bottom heat.

I like plenty of good open drainage, covered with litter or thin sods, using moist soil, well rammed down, but not "hard." We use the best fibrous loam we can secure, mixing with it about a sixth part clay, a twelfth part good wood ashes, and sometimes a little 'dry fowls' or pigeons' manure, say a 7-inch potful to a barrowload. The compost is put in long enough before planting to allow it to become warmed. In planting we use a trowel, and allow ample room to pack the soil well round the ball. The plants are from 1 foot 6 inches to 2 feet apart. Should the soil be at all dry we give it a good watering a few days before planting, and also see that the ball of each plant is thoroughly moist. About a week the whole is again watered.

Each plant is secured to a stake, and thus conducted to the trellis, and we are mindful not to tie too tightly. To grow Melons at an express pace they must have abundance of heat and moisture, 65° to 68° at night, 70° to 75° by day, with a rise of 10° by sun heat, ventilating very cautiously, and closing early to obtain as much heat as possible; 100° or 110° will not hurt, with plenty of moisture.

TRAINING.—Various methods are adopted in training Melons. First, the simple cordon; second, by topping several times. I like to top at the first wire of the trellis, taking up three leaders; by this plan more flowers are obtained for fertilisation on the same day. It is not at all difficult to get six or eight fruits to a plant. This number of fruits for small varieties might be too many where it is the desire to increase the size, though in the case of larger varieties it is preferable, as very large fruits are not always appreciated. Setting is best done in the middle of the day, when the pollen is dry and the flowers at their highest state of perfection. Care must be exercised where seed-saving is done to avoid intercrossing. For supporting the fruits I am very much in favour of nets, preferring them to boards or baskets. In watering we do it thoroughly when required, and with tepid water. Feeding may be

accomplished by the use of some well tried fertiliser, or by careful use of the drainings from the byre. Syringing is not necessary, except through the early stages of growth or in case of an attack of red spider.

As the fruits approach the ripening stage less water is supplied to the root, yet sufficient for the well-being of the plant. A drier atmosphere is also maintained, also air freely admitted. This enhances the flavour of the fruit, which is very important. Where Melons are required daily over a long season it is wise to sow about every fortnight, so that plants may be ready as required. As to diseases, canker is the worst affection of the Melon, but if the plants are grown on the plan here described the risk of this will be greatly reduced. Should it occur rub the affected part with powdered charcoal, lime, or cement. They are most liable to canker at the collar, and various means are resorted to as preventives, Knocking the bottoms out and plunging the pots in the bed is one way, keeping the rim of the pot well up above the bed, afterwards not allowing any water to come near the stem. We use leaden collars, filling these with powdered charcoal, lime, wood ashes, or sulphur.

To check red spider we syringe the plants with sulphur mixed in softsoapy water. Another pest which has caused us much anxiety is the centipede. They attack the plant at the collar and eat right up the stem if not checked. All may seem well and promising, especially if the weather be sunless, till the first bright day, when the flagging of the foliage indicates that all is not well. I find the material recommended for canker is also a hindrance to the centipede. I may add that we have lost fine Cucumber plants when covering a square yard of the trellis through this pest eating the stem entirely away. I spoke to an authority on gardening one day about the matter, but he seemed to put some doubt on my statement; and Mr. Clarke of the Yorkshire College told me that attention was now being given to the subject.

The following are good varieties of Melons:—*Scarlet flesh*, Read's Scarlet, Scarlet Premier, and Blenheim Orange; *white*, Colston Basset, Hero of Lockinge, and The Countess; *green*, Eastnor Castle. For frames Golden Perfection.

A few last jottings—1, January is early enough to make the first sowing. About four months under genial treatment are required from sowing to the ripening of the first crop. 2, Abundance of sun is required to produce the desired flavour. 3, The fruits ought to be kept a few days after cutting before sending to table. 4, Old seed is preferred to new, and will keep good for many years.—JOHN SNELL, Foreman, Grimston Park.—(Read at a meeting of the Leeds Paxton Society.)

SPRING FLOWERS AT BELVOIR.

HAVING lately had an opportunity of visiting this, the home of spring flowers, a few notes, without attempting a description of the establishment, may be of interest to those who cannot avail themselves of a similar pleasure. As is well known, owing to the kindness of the Duke and Duchess of Rutland, the flower gardens and slopes near the castle are thrown open to the public daily, Sundays included. No charge is made, and visitors are allowed to ramble at will throughout the beautiful surroundings. This is appreciated by tens of thousands during the year, and to their credit it may be said that it is only on very rare occasions that complaints have been made of damage to either flowers, plants, or trees.

A visitor was overheard to remark, "I have not missed seeing the spring flowers at Belvoir for twenty years, and they are better this season than I have ever seen them." Another, when he came in sight of the Duchess's garden for the first time, exclaimed, "It is grand." With the latter I agree, for though there were some plants, such as Hyacinths, which were past their best, the display compared favourably with former years. This must be gratifying to Mr. Divers, who succeeded the late Mr. Ingram, of world-wide repute in this particular branch of gardening, as he has tried with good effect many plants that had only previously been grown on a limited scale.

One of the best of these is *Phlox divaricata*, forming a mass of bloom not easily to be forgotten, and where Tulip Couleur de Cardinal was used in conjunction with it the combination was considered by many to be one of the most pleasing in the gardens. *Aubrietia Leichtlinii* is used extensively, as is *A. græca*. Both the above are selections, and are better than one usually sees them. *A. Ingrami*, a new variety, was blooming freely, the individual flowers of which are larger than the two latter. Another very telling bed was *Myosotis dissitiflora* and Tulip Chrysolora (yellow). Cliveden Purple Pansy and Tournesol Tulip made a pleasing combination, as also did Harbinger Primrose and Tulip Vermilion Brilliant.

In the Duchess's garden, situated on the side of a hill, and protected from the north-east and west, and open to the south, many plants and trees grow freely that are not often to be found so far north. A fine Camellia was observed in robust health and covered with bloom. Large masses of *Bambusa metake* and *B. falcata* were the picture of health, so was *Rhododendron Falconeri*, which is usually grown in a greenhouse in this country. There were also some fine specimens of the early flowering varieties of *Rhododendrons*, the majority of which were over, usually flowering here early in February. Healthy specimens of *Azara microphylla* were in bloom, and, being Vanilla scented, they quite perfumed the air for some distance from the trees. *Cunninghamia sinensis*, although growing in a sheltered spot, did not look as if it had benefited by the change from Southern China. It is an interesting curiosity, not often met with owing to its tenderness. *Berberis Darwini* was flowering freely in the surrounding woods, and I noticed one of the largest Hazel trees I have ever met with. At 5 feet from the ground it measures

upwards of 5 feet in circumference, and has a clear trunk of about 7 feet.

About two acres in front of the fruit houses in the kitchen garden are devoted to the cultivation of Alpine and other plants; over a thousand species are grown, and I need hardly say there is always something of interest in bloom. *Anemone fulgens* was a mass of bloom, though just past its best; Daffodils, which are grown by thousands, were nearly over, but the Poet's Narcissus was just bursting into flower. The Pears on the walls were in full bloom, and as they were protected from frosts there is every prospect of obtaining a good crop. Morello and May Duke Cherries were blooming satisfactorily. Cherries, by the way, do remarkably well on the clay land at Belvoir, as the wild form is to be found throughout the woods, some of which are very large specimens, and have a very pleasing effect when in bloom. The fruit trees in the orchards promise well for a heavy crop of fruit, if that all-important factor, the weather, is favourable. Many things have been omitted, but enough has been said to show how much the visit was appreciated by

—ONE OF THE CRAFT.

HABERLEA RHODOPENSIS.

ALTHOUGH by no means a new plant, having been introduced in 1880, *Haberlea rhodopensis* (fig. 92) is seldom seen in gardens. It is dwarf, resembling a *Ramondia* in habit, but with somewhat funnel-shaped flowers, 1 inch long, like a small *Streptocarpus*, the tube purple, and five white lobes. They are borne in trusses of three or four flowers each, arising from amongst the foliage. *Haberlea rhodopensis* is a native of Macedonia, and is closely related to the two genera mentioned above. In Decandolle's "Prodromus" it is placed in the family Cyrtandraceæ, between *Ramondia* and *Conandron*, both monotypic genera, *R. pyrenaica* and *C. ramondioides* being well-known garden plants. This will doubtless meet "Tyro's" requirements.

RED SPIDER ON GOOSEBERRY FOLIAGE.

THE footnote on page 418 reads, "What persons want to know who have to deal with the enemy is the safest and surest method to pursue for its extirpation." My remark above it gives a hint which might, I consider, be carried out wholesale with the least possible expense. A great consideration is the labour bill and insecticides, and their distribution. We know—at any rate I have repeated it often enough—that these pests are on the bushes in February and March, before and during the bursting of the buds. The tips of the buds are then "red with the mites," and look as though every bud infested had been dipped in red ink. They are then at our mercy, without any protection, when feeding on sunny days. At night they retire underneath the scaly matter on the old wood. Young shoots afford no protection, and therefore all useless old stuff should be pruned out and burned.

Some years ago I practically cleared my bushes in a short time with the hot suds from the tubs on washing days, in which I used a little London purple, poured over the bushes through a fine rose watering can. That is well in gardens, but to go over acres requires time, and much of it. Other ways of dealing with these pests suggest themselves to my mind, but if there is a better in the points before mentioned I shall welcome it from anyone.

Knowing by observation, and from the case I mentioned, that the spiders are sensitive to a jar, I have just been round a few bushes where I knew some existed, with the *Journal* in my left hand, and a bread-crumbs brush in my right. I brushed the foliage without damage, and caught the enclosed in a few minutes from falling, and at the same time it shows that a few of the sawfly caterpillars are there. Knowing this, I consider that if we took advantage of this habit of dropping to prevent running up the stems again, we can place either a light frame of wood, or sheet iron, or tin, divided in halves, say, 2 feet wide and 4 feet long, with a half-circular cut in the middle of each to close up with the stems, or nearly so. These traps might be dressed with some of the ordinary tree-dressing grease as used for banding for the winter moths, which could be improved perhaps by the addition of a little boiled linseed oil or turpentine. Thin paint—white for preference, as showing the quantities caught—would no doubt answer as well. The bushes after the apparatus was spread on the ground could be either shaken or brushed, so as to dislodge the enemy, and falling could be destroyed wholesale before laying their eggs very shortly to establish the pests for another season.—J. HIAM, *Astwood Bank*.

EXAMINATION IN HORTICULTURE.—As the result of the recent examination by the Royal Horticultural Society we have been favoured with a list of names of those candidates which have been successful; but as neither their address are given, nor marks appended, the publication of the list could be of small interest to our readers. If our counting is correct eighty-seven have passed in the first class, fifty-five in the second, and twenty-six in the third. "H. S. Langford" heads the list; but whether the premier belongs to the fair sex or is only a "mere man" is not stated. One of the examiners may be expected to make known some particulars in due time.

BATH AND WEST SOUTHERN COUNTIES SHOW AT SOUTHAMPTON.

THE Horticultural Show held as usual in connection with the above was held in one spacious marquee on the Southampton Common—a capital site for such an exhibition. At meetings of this Society no regular prize schedule is issued, but a grant of £100 is allowed for horticulture. This sum is placed in the capable hands of Mr. Herbert W. Fowler, with the result that a pleasing exhibition of flowers and plants is presented to the public. The tent in question measures 100 feet long, 50 feet in width. Down the centre a full row of handsome Palms are arranged, the sides being filled with a choice collection of flowering and foliage plants.

Upon entering the tent a charming group of Carnations Princess of Wales, Germania, and others meet the view, arranged as they are in an undulating manner, reflecting much credit upon the exhibitors, Messrs. W. Cutbush & Son, Highgate Nurseries, Barnet. Mr. B. Lad-

FIG. 92.—HABERLEA RHODOPENSIS.

hams, The Nurseries, Shirley, Southampton, has a charming collection of rockery plants, arranged artistically amongst natural rocks. In addition to this portion of the exhibit, Mr. Ladhams has an immense display of hardy cut flowers and Cannas. Mr. E. Wills, nurseryman, Winchester Road, Southampton, exhibits a neat collection of well grown nursery plants, Orchids, Palms, Crotons, and Spiræas, the whole forming a pleasing exhibit.

Mr. W. Peel, gardener to Miss Todd, Shirley, Southampton, has also a similar exhibit, though of smaller dimensions. At the extreme end of the tent Mr. W. H. Rogers, Red Lodge Nurseries, Southampton, arranged a magnificent collection of Rhododendrons, Azaleas, Conifers in pots, which added much to the beauty and attractiveness of the show. Mr. E. Hillier, nurseryman, Winchester, staged a choice collection of Acers and other shrubs in pots. Messrs. J. Laing & Son, Forest Hill, London, had a small but pleasing group of Begonias, Gloxinias, and Crotons.

Mr. W. J. Godfrey, Exmouth, staged Pelargoniums in pots, freely flowered and well assorted. Messrs. Barr & Sons, King Street, Covent Garden, London, had a pleasing group of cut hardy plants, Iris, Paeonies, and Poppies; Messrs. G. Paul & Son, Cheshunt, cut Rhododendrons and Lilacs; and Messrs. G. Cooling & Sons, Bath, contributed an extensive collection of cut Roses, Briars, &c., making an interesting as well as an attractive display. Messrs. Webb & Sons, Stourbridge, had a large stand in the grounds.—E. MOLYNEUX.

THE YOUNG GARDENERS' DOMAIN.

GOLD PEN-MEN.

WHILE the great majority of young gardeners who have contributed to the page set apart for them as a sort of literary "trial ground" have acquitted themselves creditably, some have naturally distinguished themselves more than others. Every article has been critically examined, and marks of merit accorded for (1) condition of MS, (2) usefulness of matter, (3) good suggestions or ideas, (4) literary merit, while deductions have been made in proportion to the extent of revision required. The result is that "H. H." (who has not given us authority for the publication of his name) and ("C. P. W.") Mr. Peter Wilkinson, Walton Lea Gardens, Warrington, obtained equal marks during the last quarter, and gold pens with fountain holders have been sent to each of them, while a book on a subject in which he is interested has been sent to "W. T., Ireland," who was only five marks below the maximum obtained: It is right to say that those writers have sent contributions that were too lengthy for the "Domain," but entitled to appear in the other columns, and these communications were rightly appraised also. "W. T." is still eligible for the quarterly pen, as are all who have not obtained one. A separate record will be kept of the merits of the contributions of those who have been unsuccessful in case the work of the seniors should be worthy of some other form of recognition in due time. All who wish to write acceptably are enjoined to preserve the number of the *Journal of Horticulture* for December 31st, 1896, and act in accordance with the advice therein contained. Their endeavours to do so will, altogether apart from any special recognition, certainly tend to their advantage in after life. We can scarcely expect young gardeners to be so diligent with their pens in the summer as during the winter, for they are entitled to healthy recreation. The extent of this must be governed by their own judgment. What we desire is that the next generation of gardeners shall be better and more accomplished than the past. The status of the craft can only be raised by the diligence of its younger members.

FORCING FRENCH BEANS.

FOR early work drain the pots fairly well, and as the season advances one crock with rough siftings suffices. We half fill the pots with soil, leaving room for ample top-dressing. Having tried both methods, "Stone Warrilow's" and "W. W.'s," I prefer the former to the latter, and I do not think "W. W." would pick beans two weeks in advance by his method, which entails two pottings and more work with no better results. Unless his chief has more men than work, which is most unlikely, the twice potting is hardly worth extra trouble; but perhaps he is like the squire in preferring something old-fashioned.—SINGLE W.

[Has "Single W." found the plants to emit roots from the stems after the second filling in of soil?]

NATURE'S LARDER.

(Concluded from page 43.)

WATER-LOGGED land is suitable only for aquatic or bog plants. Land not waterlogged, yet moist, or too slow in filtering off excess, is still unfit to grow healthy plants, shrubs, or trees. The water fills each tube and pore in the soil; this evaporates slowly and cools the soil; it hinders the decay of organic matter, also of root action. When the water disappears it generally leaves a surface which bakes and cracks in sunny weather. Water is heaviest at a temperature of 40° Fahr., and therefore the cold water from winter snows and ice retaining its position in the soil, the warm summer rains cannot descend, while solar heat penetrates to no appreciable depth. Now we see that by drainage we allow water, the grand dissolving and mellowing agent, to trickle through the soil, drawing air after it to every passage it has passed.

The mechanism, so to speak, thus set in motion sweetly progresses. Oxides are formed, likewise acids, and by further action the phosphates, nitrates, and carbonates, while the dissolution of organic matter becomes more sure and reliable. The sun's rays heat the surface soil, warm rains fall and carry warmth downwards, obnoxious matters are washed from the soil, and bacterial with other agencies encouraged.

The burning of soils has been referred to by Mr. Dyke. Speaking of bacteria, we may state their action ceases in cold wet soils. Nitrification, or the work of bacteria, is briskest in a soil where the temperature is 90° Fahr., though from 40° up to 120° the process has been proved. Sufficiency of moisture is retained during dry weather in drained lands, water rising from below by capillary attraction. Capillary attraction is the power which very minute tubes possess of causing a liquid to rise in them above its level, sometimes as much as 12 or 15 inches. To promote these fertilising agents lime and an alkaline condition of soil is regarded as necessary.

Lime to most soils is highly beneficial. To improve heavy soils or those with an excess of organic constituents, we apply lime. It neutralises the acids which tend to sour a soil. It liberates the potash and soda from heavy land, also it frees nitrogen from organic substances, this forming ammonia and nitric acid. With this acid lime combines to form calcium nitrate. Lime then is valuable. By the bacterial agents aforementioned, matter for ready absorption is prepared.

The fertility of soils depends on three conditions: 1, The physical condition—viz., lightness or stiffness; evaporative power; water-retaining power; capacity for heat; colour. 2, Its chemical condition; referring to its constituents and quantities of soluble or insoluble matter. 3, The biological condition. We have oxidising bacteria, those of a reverse nature, called reducing bacteria, bacteria which tend to retain nitrogen in soils.

Besides these, worms, grubs of all kinds and various larva all tend to aid in the pulverisation. How delightful to have even the rudiments of agricultural chemistry, and how profitable in our culture. Armed with a few scientific facts we need only to concentrate our reasoning powers in cases of perplexity, coupling these facts with those gained by careful observation in practice, we must surely triumph over the principles relating to the "food stores," or "Nature's larder."—A YOUNG SCOT.

IXORAS.

THESE plants are worth more attention than they generally receive. They are effective when well grown, either as small or large plants. They may be increased by cuttings, which I find root best in the autumn where the heat is limited, although they will root at any time of the year if sufficient heat is available. They are best inserted singly in small pots, filled with fine peat and coarse sand. If large plants are required ample root room must be afforded, but good decorative plants are grown in 6-inch pots of the smaller flowered varieties. The varieties with large trusses of blooms, of which Duffii Williamsi are a type, make the best specimens. Ixoras require brisk heat and copious moisture during the growing season, always shading from bright sun. A good compost to grow them in consists of two parts peat, one of loam, with charcoal and coarse sand added, top-dressing at intervals with some well-approved artificial manure. The plants should be kept well up to the glass when starting into growth, so as to obtain an even break. If one or two of the shoots are growing stronger than the others take out the point, otherwise one part of the plant will be in flower before the other.

To grow Ixoras well they must be kept clean and free from insect pests. A thorough cleaning should be given before they start into growth, as the young shoots and leaves are very tender and liable to get injured. They should be carefully gone over frequently, killing all insects that can be seen by touching with a drop of methylated spirit. Mealy bug and scale are the greatest enemies of Ixoras. A start should be made with clean young plants if possible, as the bark of the old wood greatly harbours insect pests. When the plants are in flower they should be removed to a drier and cooler house, in which they retain their beauty for a considerable time.—J. L. G.

ZONAL PELARGONIUMS.

Now is the time to insert cuttings of Zonal Pelargoniums that are to flower next winter, if not already done. March and April are the best months. It is best to insert the cuttings singly in 3-inch pots at this rather late period, subsequently shifting the plants into 5 and 6-inch pots when rooted, afterwards repotting the best into 7-inch pots if large plants are required.

For rooting the cuttings use a compost of equal parts of loam, leaf mould, and sand. For the flowering pots use three-fourths loam and one-fourth of leaf mould and horse droppings, with an 8-inch potful of bonemeal to each barrowload of soil. Stand the plants in an open sunny position outside during July and August, and if September is fine till the middle of that month. Pinch off the flower buds that show till the end of August. Use liquid manure sparingly till the flower trusses advance for opening, when it may be given freely when needed.

Some of the best though old varieties for flowering in winter time are—Singles: Charles Dickens, D. B. Crane, General Dodds, Miller's Favourite, Brilliantissima, Lord Salisbury, very dark; and Wm. Dobbs, scarlet; Agnes, Sir Percival, Swanley Single White, and Edith Syrratt white; Mrs. Robt. Cannell, Beauty of Kent, Mrs. Norman, Lady Rosebery, and Mrs. H. A. Needs, salmon; Mrs. G. Slatter and Mrs. Wildsmith, pink; Mrs. W. Wright, a deep magenta, supposed to be the nearest approach to blue in the family.

In the doubles we have useful plants either for cut flowers, as the flowers last so well, or for making the greenhouse gay over a long period. I do not know any better varieties for winter blooming than A. D. Raspail and Raspail Improved, Golden Rain, Turtle's Surprise, M. Briant, and Mr. W. E. Gladstone, scarlet; H. M. Stanley, Lord Derby, and Mrs. Dixon, pink; Swanley Double White, White Abney, and La Sygne, white; Maggie Hallock, Lord Tennyson, and Beauté Poitevin, salmon; Miller's Gem, magenta, and Madame L. Dalloy, blush.

A mistake is often made keeping the plants in too low a temperature during the winter. Do not let the thermometer fall below 55° with a dry buoyant air, and you will have flowers in abundance even in the dark days about Christmas.—W. T., Ireland.

A FEW STOVE CLIMBERS AND THEIR CULTURE.

WE young gardeners ought to be a little ashamed of ourselves if we do not take advantage of the opportunity such as is now provided for expressing our ideas, and helping one another by giving our experiences through the medium of the Journal. Hence have I been drawn out of my shell, and I hope if anyone thinks I am wrong he will correct me as far as it lies in his power to do so. To undertake an article on the whole class of stove climbers would be rather large under-

taking, in fact it would be too large for most "youngsters," that is why I have said a "few" stove climbers.

I think *Stephanotis floribunda* should have the preference, for what can compare with the pure wax-like flowers and sweet perfume of this valuable plant? The compost we use for growing it consists of two parts fibrous loam, one part peat, half part leaf soil, with a sprinkling of silver sand and charcoal added. When the plants are fairly established in this compost we feed continually to encourage sturdy growth, which flowers freely; the plants then only require keeping free from mealy bug and other insect pests to be fully appreciated. For syringing we use petroleum to the extent of one wineglass (about 1½ oz.) to a gallon of water, keeping thoroughly mixed with the syringe whilst using. By two or three syringings weekly not an insect is seen, while the plant is in no way injured. The growths as they extend must be tied down at least once a week, or the plant will become a perfect thicket, the growth is so rapid. This constant tying down facilitates pruning later in the season, as by keeping the growths free, and preventing entangling all the wood that is not required after flowering can be easily cut out, leaving just enough under the direct action of light to furnish the plant for another season.

Next to the *Stephanotis* comes *Gloriosa superba*, or at least it does in my estimation. The compost we use for this is as follows:—Three parts peat, one part good fibrous loam, half part dried cow manure, and half part coarse silver sand. We find that the end of April is soon enough to start the tubers, which is done by placing the pots in the propagating case until the growths are about 1 foot long. The plants are then removed to the stove, summer training the growths as they extend along the roof. Red spider and thrips are the chief enemies to guard against. It will not be a very difficult matter to keep down these if the syringe is kept going pretty freely. When the leaves change in the autumn water is withheld until another season.

Third on the list comes *Allamanda*. The compost for this consists chiefly of rich loam with a little dried cow manure passed through a coarse riddle. If the loam is not fibrous a small portion (about a fourth part) of peat may be added. A great mistake is made by some growers who are anxious to make fine specimens by tying down the growths too soon. By allowing them to remain as they grow, as they are kept just clear of the glass, they show flower buds much sooner than when tied down tightly, the tying down seeming to encourage growth rather than flowers. When the plant has commenced flowering in earnest a top-dressing of some good artificial manure is very beneficial.

To keep the flowers fresh in a cut state they should have about a tablespoonful of water placed inside them, and be also stood in water. In this way they may be kept for several days. Of course this is not necessary where a good plant flowers so freely that quantities may be cut every day. As November advances dry off for about ten weeks, which is quite sufficient rest. Prune rather hard, and start again about the middle of January.

Dipladenias next demand mention. There are some real gems in this class, notably those mentioned by Mr. Lock in the *Journal* of April 22nd, and young gardeners cannot do better than follow his cultural directions. The only exception I take to Mr. L.'s *modus operandi* is that he spends unnecessary time in sponging. I think if he adopted the practice described in the case of the *Stephanotis* he would save much time, and find the result equally satisfactory.

Although we cannot, strictly speaking, class *Asparagus plumosus* as a climber, yet it comes in very useful for covering pillars of any height up to 10 feet, so I will give a few hints as to how we grow it. If a new stock is required and an old plant is not obtainable, plants can be raised from seeds, but these being extremely hard it is well to soak them for a day or two before sowing, as by doing so they germinate the more freely. Sow the seeds in pots in a compost of peat, leaf soil, and sand in equal parts, placing them in a temperature of 80° or 85°.

If an old plant is obtainable a better start can be made by division, cutting the plant up with a sharp knife, being sure to have roots to each portion, which place in pots of suitable size, putting them in the propagating case until growth starts freely. A suitable compost is formed by three parts of good peat, one part of old Mushroom bed refuse, and one part of sand. The plants require syringing occasionally to keep down scale, which is the most troublesome enemy, and is rather a difficult one to get rid of without damaging the fine leaves, when once it is there. Many more very valuable stove climbers could be mentioned, but these are a few of the favourites of—GARCON.

RANUNCULUS GRANDIFOLIUS.—Of the many species of *Ranunculus*, this, from the Canary Islands, is one of the most handsome. Although not perfectly hardy, it can be grown outside during the summer, wintered in a cold frame, and flowered in a cool house in April and May. Possibly if tried in the south-west counties of England or Ireland, it would be found to stand uninjured outside through the winter. The leaves are of immense size, the radical ones often being more than 1 foot across. They are almost reniform in shape, with deeply lobed and serrated margins, both surfaces being covered with fine soft hairs. The largest of the stem leaves are about 9 inches across, and like the others in shape. The flowers are produced on branching stems 2½ to 3 feet in height, fifty to seventy flowers being produced on one stem. The individual blossoms are 2 inches across, and similar to our wild Buttercup in colour. At Kew several plants may be seen in flower in pots in the greenhouse, and others established in a border in the Winter Garden.—K.

FRUIT FORCING.

Cherry House.—There is nothing in the fruit way so charming at this time of year as a house of Cherries, whether the trees are planted out and trained to trellises, or grown in pots as standards. No greater mistake is made than having a number of varieties for affording a general supply, and a long succession of fruit can be had by forcing such as Early Rivers, Governor Wood, and Black Tartarian. When the whole of the crop is ripe the chief consideration will be to keep the fruit fresh, and prolong the season as long as possible. Shading will do so, but it is only advisable when the Cherries are directly exposed to the sun, owing to the limited foliage. Free ventilation must be attended to, and in hot weather a sprinkling of water on the surface of the border, as well as the paths, in the hottest part of the day, will assist in keeping the fruit plump. The supply of water must not be neglected, for dryness at the roots is inimical to the formation of the buds for the ensuing crop of fruit and health of the trees.

Cucumbers.—In these days of express culture, and their frequent breakdowns, it may appear retrograde to advise the renovation of plants that have been in bearing since the beginning of the year. If the old plants have not been cropped within an inch of their lives (which is always the rate of progress under the go-as-fast-as-possible break-neck system) and are fairly healthy, they may be kept in satisfactory bearing a time longer by removing some of the soil with a fork, and supplying in its place lumpy loam, afterwards surfacing with decayed manure, and, after sprinkling on it half a pound per square yard of a mixture of air-slaked best chalk lime and dry soot in equal parts by measure, giving a good soaking of tepid water. This will afford such amounts of the essential elements and minor constituents of Cucumbers, to which the plants are little accustomed in these go-a-head times, that they will recover from the lethargy of overbearing, and make growths bearing fruit abundantly. Then it is only a question of feeding—the supplying of phosphoric and potassic elements, with nitrogenic, to insure their utilisation.

If the plants are on their last legs, devoured by red spider, cankered in the stem, and altogether "out of sorts," then by all means clear them out of the way, cleanse the house, take out the old soil, place in fresh and sound, and plant as soon as possible with young healthy plants just coming into bearing in order to save time.

In the matter of plants of this year's raising it will be necessary to thin out the old growths and encourage young in their place. Shade from powerful sun, syringe both ways in the morning and early afternoon, damping well down before nightfall. Admit a little air at 75°, increasing with the advancing sun, keeping at 85° to 90° through the day with sun, and close early so as to secure a temperature of 90°, 95°, or even 100° well on in the afternoon. Fire heat need only be employed to prevent the night temperature falling below 60° to 65°, and to insure 70° to 75° by day.

Pits and Frames.—Cucumbers in these should be ventilated from 7.30 to 8 A.M., just a little to allow the pent-up moisture to escape and the atmosphere to warm gradually with the advancing sun. In the hottest part of the day a slight shade from fierce sun will be beneficial, and keeping through the day at 85° to 90°, close so as to increase 5° to 10° with sun heat. Keep the plants watered as required, about twice a week will be necessary in bright weather, and damp overhead on fine afternoons. Avoid overcrowding the foliage, thinning well, keeping up a succession of bearing wood, removing bad leaves, stopping one or two joints beyond the show of fruit, and avoid overcropping. If straight fruits are wanted place them in glasses or pieces of quarter-inch deal, nailed together so as to form open-ended troughs about 3 inches wide, which must be slightly inclined so as not to hold water.

Figs.—*Early Forced Planted-out Trees.*—The fruits on these are now ripening, and must be kept from wet, as this not only causes them to crack, but ruins the quality, and often induces their spotting at the apex, a salmon coloured spot forming in consequence of attack by the spot fungus, *Gaeosporium laticolor*. The best preventive of this is a little air constantly so that moisture does not condense on the fruit during the night, and the ventilation being increased early in the day there will not be any accumulated moisture such as is essential for the germination of the fungus spores. A temperature of 60° to 65° at night, and 70° to 75° by day, artificially, will be sufficient, advancing to 85° or 90° from sun heat. Afford moderate air moisture by damping the paths and borders when they become dry, and supply water to the roots so as to keep the foliage in health.

Melons.—Plants ripening their fruit should have water withheld from it, and only sufficient given at the roots to keep the foliage fresh. A little air constantly, gentle warmth in the hot-water pipes, and rather free ventilation, increased from the early part of the day, is the best safeguard against the fruit cracking. If there be any danger of this cut the Vine about half-way through a short distance below the fruit, but the chief thing is to keep the atmosphere airing, and thus cause evaporation

from instead of the condensation of moisture upon it. Plants in flower also must have a little air constantly, with a free circulation on fine days, fertilising the flowers as they become fully expanded, and when a sufficient number of fruits about equal size are set upon a plant remove all others and flowers, both staminate and pistillate. Three or four fruits on plants of ordinary size and vigour are as many as each can bring to full size and highest perfection, overcropping being alike fatal to appearance and utility, the fruit very often not reaching maturity, but ripens prematurely, and these are comparatively worthless. Plants swelling their fruits should have liberal supplies of tepid liquid manure or light top-dressings of fertiliser worked in moderately, with additions made to the ridges or hillocks of fresh soil as the roots protrude, and it should be warm. Go over the plants frequently for the removal or stopping of laterals, keeping the principal foliage well exposed to light, and above all things perfectly free from pests.

Young plants in frames or pits with the shoots trained over the surface must be thinned to four, two being taken to the front and two to the back, keeping the laterals rubbed off to quite 6 inches from the stem, and pinching the main shoots when 12 to 15 inches from the sides of the pits or frames. The laterals will show fruit at the first or second joint, and the flowers being fully expanded fertilise them about noon on a fine day, leaving a little air on constantly to prevent the condensation of moisture, a moist close atmosphere being fatal to a good set. Pinch out the points of the shoots one joint above the fruit, and after three or four fruits are set and swelling on a plant remove all others. Keep the laterals closely pinched, and thin them if likely to crowd the principal foliage. Afford due but not excessive supplies of water, and if liquid manure be given, let it be weak and warm, keeping it from the foliage. Sprinkle the plants in the afternoon of fine days with clear soft water, closing about 3.30 P.M. to 4 P.M., or so early as to raise the temperature to 90°, 95°, or 100°, and ventilate early in the day, or from 7.30 A.M. to 8 A.M., keeping through the day at 80° to 90°, and reduce the ventilation gradually. Keep a sharp look out for aphides, and fumigate on two or three consecutive evenings moderately, an overdose doing great injury. Shade the following day if the weather be bright, and always have the foliage dry when fumigating. Red spider will not appear if the plants are kept properly moist, but if it does so place a little flowers of sulphur on a slate raised on an inverted flower pot so that the sun can act upon it. If canker appear on the stem rub quicklime into the affected parts until they are dry, and repeat as occasion requires, being careful to keep water from the collar.

THE KITCHEN GARDEN.

Tomatoes.—Bright sunshine accompanied by parching winds, though favourable to the ripening of fruit, is not altogether to the advantage of Tomato growers. The fruit on plants under glass does not set so well on the later formed bunches as it does when the weather is less trying, especially where the ventilation and other treatment have not been varied to meet the requirements of the case. Top ventilators should be opened a few inches not later than 6 A.M., gradually opening them wider till at ten o'clock, when ample provision has been made. Defer ventilating till the temperature has run up to 70° or more, and the chances are nothing short of opening both top and side ventilators to their full extent will lower the heat sufficiently. By opening early it is scarcely necessary to admit any front or side air, or even to set the top ventilators open to their full extent before June. Early ventilation also favours exemption from disease. A portion of the air may be taken off at 5 P.M., but the houses must not be wholly closed early enough to create a heated, moisture-laden atmosphere, as the cladisporium revels in this. All watering of borders should be done as much as possible in the morning, and, if not already done, mulched with strawy manure, this saving the watering pot or hose and keeping the atmosphere drier. After the plants have become furnished with two or more clusters of fruit they must be fed freely at the roots, also receiving abundance of water, otherwise they will fail to set and swell successional clusters of fruit. All ought to be gone over at least once a week, removing all superfluous growths, training the leaders, and slightly reducing the size of the leaves where these shade the fruit unduly. Setting of fruit should not be left to chance or artificial distribution of pollen, accomplished by smartly tapping the stems with a padded stick, be deferred till late in the day. About ten o'clock is a good time to commence, or before the moisture on the stigma of each flower has disappeared.

Tomatoes in Pots.—These are among the first to suffer from the effects of drying winds and strong sunshine. If the pots are arranged on stagings, benches, or boards, and are further exposed to sunshine, they become very hot and the soil dries rapidly. They are liable to fail, even if watered three or four times a day. Covering the pots with mats, paper, or strawy litter keeps them somewhat cooler, but they will still need abundance of water and liquid manure. Top-dressings of rich manure and loam are of good service, but not if they are taken much notice of when examined before watering, as its appearance may be deceptive. The plants ought to receive nearly or quite as much water after a top-dressing has been applied as they did before it was given. Pots ought, where possible, to be arranged either on a bed of soil or ashes, and the roots allowed to ramble out through the drainage holes into this. Ashes answer admirably if kept constantly moist, an occasional surfacing of special manure adding materially to the cropping capabilities of the plants. Topping weakly plants beyond the third or fourth bunch of flowers favours rapid swelling and early ripening of crops, and if there is sufficient head room a fresh leader can be laid in from the next break.

Potatoes.—Where badly damaged by frost before they had been moulded up once recovery has been slow, and in some instances the wisest plan would have been to plant afresh. Potatoes planted late are growing strongly, and with a change to moister weather with warm nights rapid progress will be made. Whilst the dry hot weather lasts hoeing deeply among them would in many instances do more harm than good. Deep hoeing is also unwise after the fibrous roots are in full possession of the spaces between the rows. Advantage ought to be taken of a change to showery weather to sow either soot freely or special manures lightly among the rows, then hoeing and soon after moulding up the plants.

Planting Between Potatoes.—Where the rows of short-topped early Potatoes are not less than 3 feet apart, good sites for rows of Borecole, autumn Broccoli, and Cauliflower and Brussels Sprouts are ready directly after the Potatoes have had the soil ridged up to them. In anticipation of this the requisite number of plants should have been raised under glass and duly pricked out on sheltered borders. From these they ought to be transplanted with a trowel, saving a small ball of soil about the roots. They will move best if well moistened at the roots a few hours prior to lifting, and should be firmly replanted with the trowel at distances of 2 feet or rather more apart. If this is done in dry weather they must be watered frequently, ceasing when they are growing strongly.

Peas.—Only the more robust varieties, of the Ne Plus Ultra and British Queen types, should be sown now. The more feeble sorts late sown succumb quickly to mildew. Sow thinly in freely manured, deeply dug ground. A mulching of strawy manure ought where possible to be applied to all the midseason and late rows of Peas, and would not be wasted on the earlier rows. If water or liquid manure is given let it be in sufficiently heavy quantities to thoroughly moisten the ground.

Spinach.—This fails quickly in hot and dry weather, but if required in August the next two or three sowings should be made at fortnightly intervals on a well manured north border. The soil should be got into a finely divided state, and when the shallow drills, opened at 12 inches apart, are found dry, moisten prior to sowing the seed. Avoid sowing thickly. The large-leaved Victoria or Monstrous Viroflay is to be preferred for these sowings.

New Zealand Spinach.—This is but a poor substitute for true Spinach, but proves acceptable in some establishments. Its cultural requirements are of the simplest character. A dozen plants raised under glass, and transplanted to a south border or a sunny open spot, will yield bushels of succulent tops. Plant a yard apart each way, and give water occasionally till the roots have spread out into the surrounding soil.

Turnips.—These also are liable to fail during a hot summer, but are less likely to do so if the seed is sown on a cool rich border—a moderately wide north border answering well.

STERNBERGIA FISCHERIANA.—This is a spring-flowering species of the well-known Winter Daffodil, and as it now appears in the border is a noticeable flower, even though it comes in Narcissus time, when yellow flowers are becoming plentiful. Sternbergia Fischeriana differs from the autumn-flowering *S. lutea* in having much broader leaves, smaller flowers of the same rich yellow colour. The peduncles are short, and the flowers are borne above the leaves, which as yet are only slightly developed in height. The plant flowers freely, each bulb producing several blooms. The Sternbergias are all valuable bulbous plants in any garden and are perfectly hardy, even the leaves of *S. lutea*, which are in evidence all the winter and only ripen at this season, being unaffected by the rigours. That they are not more grown is probably owing to their need of a special position in the border, which they do not always find. As *S. lutea* now ripens it requires a position where it will be fairly dry, and a warm place where it will be well roasted in summer. In such a position, in rather heavy soil, it has, says a writer in an American contemporary, never disappointed me, and it starts in due time in the late fall and blossoms profusely, and even multiplies. The large-flowered *S. macrantha*, which follows this species in flower, evidently requires the same kind of location, for several clumps planted in other conditions here have as yet failed to do much in the way of flowering, though the leaves are now prominent enough.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE past winter and spring will be long remembered by bee-keepers as being very disastrous to the bees, not as is sometimes the case when only certain localities suffered, but throughout the country reports are daily to hand as to the backwardness of stocks when compared with other seasons. A gardener in one of the largest places in the West of England, where fruit is extensively grown, and who devotes much attention to his bees, says, "At the present moment the honey harvest for this year is gloomy; but let us hope—that is all we can do. Owing to the high winds and cold

weather many bees left their hives at various times and never returned; hundreds were observed lying benumbed on the walks, beaten down by the wind whilst returning home laden with pollen, and all around this neighbourhood bee-keepers have the same story to tell. Hives that appeared to be strong in bees six weeks ago have dwindled, and are now weaker than at that time."

Reports from the midland and northern districts confirm the above; but I do not agree with the writer that "to hope is all we can do," as it is at such times when the attentive bee-keeper is able to assist his bees. As a proof I may mention what has been done in my own apiary during the inclement weather experienced this spring. Bees were fed daily with thin syrup placed in open-air feeders near the hives; this proved an advantage, and was the means of keeping them near home.

When a favourable change came in the weather, which it did on the 15th inst. and two following days, it was fine and bright, the maximum temperature being 69° in the shade, the bees worked with a will as if intending to make up for loss of time. Entrances had to be opened their full width, and colonies that had not been opened for several weeks, and from which few bees had been observed on the wing, were now found to be overflowing with bees, showing that the few stones of sugar that had been distributed throughout the apiary had had the desired effect of keeping the queens laying, which will in due course be, doubtless, returned a hundredfold.

Contrast this with the let-alone system, and it must be apparent to the most casual observer that the thoughtful bee-keeper will be well repaid for the extra trouble and expense he devotes to his bees. The Apple trees are now in full bloom, and so are the Sycamores. From these sources alone honey and pollen are being obtained in abundance. The Strawberries, too, will soon be a mass of bloom, from which the bees will derive much benefit. If the fine weather continue strong colonies will at once store a surplus, but weak stocks will only store sufficient for their daily requirements.

WORKING FOR COMB HONEY.

Except in favoured districts, or where bees have received careful attention, few stocks will be in condition for supering. It is useless placing crates of sections in a hive unless the brood nest is crowded with bees. This is the reason why bee-keepers often have a difficulty in getting their bees to work in supers. If a stock is fairly strong in bees during a spell of fine weather, when the fruit trees are in bloom, it is possible to obtain some well finished early sections from that source. This is done by contracting the brood nest. First remove all the outside combs that do not contain brood and close up the division board. Care must be taken that the bees cannot gain access to the empty space, or they will fill it with combs.

I recently had a practical illustration of this. In looking through a hive from which some frames had been removed, and the space not filled with other frames, although it had only been done a few days previously, the empty space was being rapidly filled with comb, which had to be destroyed. Had no empty space been left in the brood nest all would have been well, and much valuable time to the bees have been saved. In placing a crate of sections on the top of the frames, which should always be put directly over the brood nest, the crate fitting closely on the top bar of frames, excluder zinc need not be used, as the queen will not pass over the sealed-up stores at the top of the combs to lay eggs in the sections above. Cover the whole up with several thicknesses of old carpet, or some warm material, as it is necessary to keep the whole as warm as it is possible, otherwise the bees will not work in supers.

This plan of obtaining early sections is only recommended in exceptional cases. Stocks worked on this plan should have additional frames of comb or foundation given to them as required, otherwise the laying powers of the queen will be restricted, and the colony will thus be short of workers when the honey flow comes.

If honey cannot be obtained freely from other sources, after the fruit tree blossom is over till the White Clover comes in, it will be an advantage to remove the crate of sections altogether, and fill the body of the hive with frames, the sections to be afterwards returned to the hive as soon as honey is again coming in freely. Early sections may also be obtained by placing a frame of sections at the back of brood nest with a piece of excluder zinc between to prevent the queen laying in them.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUE RECEIVED.

F. Sander & Co., St. Albans.—*New Orchids—New Plants.*

* All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Grapes Scalded (H., Kent).—The specimens arrived on Wednesday morning. We can only say the misfortune is the result of too late (and too full at once) ventilation on a bright morning after one of the cold nights we have had, and consequently too low temperature for the Grapes. The other varieties have had a narrow escape.

Swollen Pears (C. W.).—If you examine the fruits inside you will find maggots, the larvæ of the Pear midge referred to in a note by Mr. Hiam on page 463, and about which Mr. Abbey will perhaps favour with some further particulars. In the meantime follow Mr. Hiam's advice, and burn all the abnormal Pears.

Cabbage and Cauliflower Leaves Diseased (T. G.).—There were no less than three parasitic fungi on the leaves—namely, the Cabbage rot fungus, *Peronospora parasitica*; the scurvy grass (*Cochlearia officinalis*) rot fungus, *Ovularia cochleariae*, Mass.; and the Turnip rot fungus, *Botrytis vulgaris*. No dressings of sulphate of copper can well be applied to vegetables nearly ready for use, otherwise we found dusting with it very effective on Seakale and Horseradish, the latter often leaving the leaves ruined by the allied species of spot fungus, *Ovularia armoraciae*, Mass. In the case of Cabbage we found the following treatment act well. (1) Burn all affected leaves and stumps. (2) Apply to the land a dressing of the following mixture:—Dissolved raw bones, 3 cwt.; bonemeal, 1 cwt.; mixed, per acre, or 2½ lb. per rod. Before planting, and as soon as the plants get hold of the soil, apply the following mixture:—Nitrate of soda, 2 cwt.; common salt, 3 cwt.; mixed, per acre, or 3½ lb. per rod, keeping from the hearts of the plants. A further dressing of nitrate of soda early in the spring acted like magic, and repaid its cost thrice over.

Young Defective Bunches of Grapes (Peccavi).—The grey mould on the affected parts is the Vine mould, *Sclerotinia Fuckeliana*, in the conidial condition, and then known as *Botrytis cinerea*. It is the most decisive case of shanking being caused by the fungus that has come to our notice, the hyphæ being both outside and within the tissues of the tender bunch stem and lateral stems of the bunch, these being completely girdled by the mycelial hyphæ. The fungus is very partial to Muscat of Alexandria and Gros Colman, also ripening bunches of Alicante. The parasite has, no doubt, passed the winter on the Vines in the sclerotium stage, the externally black sclerotia being seated on the wood, where they may be destroyed or the recurrence of the disease prevented by dressing the rods in the winter with a solution of sulphate of iron, 1 lb. to 1½ gallon of water, applying with a half-worn clean painter's sash brush. The Vines may also be sprayed when they come into leaf with a solution of Condry's fluid, using a tablespoonful to a quart of water, and applying by means of an atomiser, the smallest possible film sufficing, repeating at intervals of about three weeks. It is not unusual for Muscat of Alexandria to be affected, whilst Mrs. Pince in the same house is perfectly free. Probably that condition favourable to attacks of the fungus has been induced by too much water at the roots, or too rich supplies of nourishment in the early stages of growth, with too close and moist an atmosphere, the house having been kept closer than would have been the case had the weather been less windy and cold than it has been of late. We should apply some good commercial fertiliser and get the wood more firm; then we do not consider you have anything to fear in the future, providing the border is sound and properly drained, other conditions, of course, being favourable to the health of the Vines, for on that depends their resistance of the fungus.

"New" Method of Grafting (M. S.).—We are not surprised by your exclamation, "What! again the old saddle-graft brought forward as a new method, and this by the R.H.S.!" (page 430). The scientific gentlemen composing the Committee could not be expected to be conversant with all old practical matters, but it is a little astonishing that Mr. Douglas regarded the method as something like a "new" improvement. It is a modification of the very old saddle-grafting, and we found it excellent many years ago. We congratulate you on saving your Strawberry blooms by netting to "break" the frost.

Propagating Boronias (H. H. B. W.).—You are not alone in your liking for the deliciously fragrant Boronias. When the young shoots are about half ripened is the time to make and insert cuttings. The pots for their reception must be well drained and firmly filled with fine peaty soil, heavily surfaced with sharp sand. Trim the cuttings with a keen knife, inserting firmly 2 inches apart, and give a gentle watering at once. Place in an intermediate temperature or warm greenhouse, and closely cover with a bell-glass. Shade from bright sunshine, and thoroughly dry the glass every morning. They will root and commence to grow in a few weeks, when they should be topped, and after breaking afresh be potted into thumb pots, using a compost of two parts of fibrous peat to one of light loam, charcoal and silver sand being freely added. Apply water carefully, pinch back repeatedly, and bushy little plants will result.

Vagaries in Laburnums (H. C.).—We have seen several trees similar to yours, though they are not common in gardens. It is known as *Cytisus Adami*, and is a graft hybrid between *C. Laburnum* and *C. purpureus*, obtained by Mr. Jean Louis Adam in 1825 in establishing the purple species on the common Laburnum. In this process it is supposed that a cell of the one species became divided and united to a cell of the other, and the result has been a plant producing not only flowers of each species separately, but others partaking of the characters of both. There are other instances in the vegetable kingdom in which a similar union of cells is believed to have taken place, but *Cytisus Adami* is the best known and best established. It is remarkable that grafting or budding with one variety will occasionally, as the tree grows, produce three or four forms differing in colour and the character of the leaves and racemes. We have not only seen purple and yellow flowers on the same tree but about half and half in the same raceme. There is no accounting for the vagaries of Laburnums when grafting has been resorted to.

Strawberry Leaves Diseased (T. G.).—The leaves are badly infested with the Strawberry leaf-blight fungus, *Sphaerella fragariae* which first appears on the upper surface of the leaves in the shape of small reddish purple spots, these increasing rapidly in size. The centres gradually become lighter, afterwards turn brown, but the margin or boundary remains purplish red. The spots vary in size, from a quarter inch, but sometimes run together, forming large discoloured blotches. Badly infested leaves finally wither, turn brown, and die. The spores of the fungus must be killed in the act of germinating, and the way to do it is to coat the leaf surface with a thin film of sulphate of copper preparation in powder, such as fostite and anti-blight, applying with a bellows apparatus two or more times during summer, say when the crop is gathered, just after the old runners and bad leaves are cut off, so as to coat the young leaves, repeating when necessary. This has a very decided effect on the fungus. Then in the spring, when the new leaves start, whether under glass or outdoors, dust the plants, and again just before the flowers open. We have found this treatment troublesome, but very satisfactory both against this fungus and mildew, *Oidium balsami*. It should be needless to say that old infested leaves should be removed and burnt so as to destroy the resting receptacles of the parasite, which is becoming very common in England, probably being introduced from America, as it does not occur on the wild Strawberry.

Destroying Ants (J. F. W.).—The black ants with wings are the male and female representatives, and only appear once a year, the females divesting themselves of the wings after mating while the males die. Thus all are wingless at other times, but form three classes—(1) workers, (2) soldiers, and (3) queen. Now, to get at the latter is the real business in the way of extirpation, for killing the workers only lessens—does not root out the evil. Thus the point is to give the workers something they can take home, and there transfer it to the larvae, in feeding them, so that the whole may get "smaller by degrees and beautifully less." The safest preparation is calomel and sugar, one part of the first to ten parts of finely powdered loaf sugar, mixed together and laid in small heaps about their nests and runs. The ants eat it and die, but it is most efficacious in the spring. The following never fails, but it is a very dangerous poison. Place 1 oz. of white arsenic in an old iron pot with a quart of water, and boil until reduced to a pint or a little more of liquid, then add $\frac{1}{2}$ lb. of coarse sugar. This mixture can be placed in saucers or dropped about their runs, exercising the utmost caution. If you do not care to prepare such mixture, Ballikinrain ant destroyer will do the work effectually. Carbolic acid, No. 5, diluted with twelve times its bulk of water, sprinkled over places where there is not any vegetation, will drive the ants away, but its smell prevents its use indoors. Not so camphor, a piece about the size of a Filbert placed in 2 quarts of hot water, and when cool enough applied by means of an atomiser will kill all it touches. So also will aniline, one part in twenty parts water, using in a similar manner. This has practically no smell, and stains very little. Fir tree oil is also effective, but scarcely available for use indoors.

Treatment of Camellias (Liverpoolian).—Certainly, if the Camellias are making a good growth they may be shifted into larger pots now or just after the buds set, and whilst quite small; but if not growing freely leave them as they are for another year, unless they are very much root-bound, when they may be potted. Camellias and all hardwooded plants are always best when rather under than over-potted. A size larger pot is all that should be given at one time, and Camellias do not require this oftener than once in every second or third year. Turfy loam and fibrous peat in equal parts, with a little leaf soil or old cow manure, and a free admixture of sand, providing efficient drainage, grow these plants well. The more fibrous the loam and peat, both of which should be light rather than heavy or spongy, the better.

Propagating Aubrietias (Amateur).—You will find it a very simple matter to raise any number of these charming spring-flowering plants. Thousands, possibly millions, have been raised from seeds, and this is certainly the easiest way; and although all the resulting plants are not precisely alike in the size of the flowers and in the habit of growth, the diversity is not so great as to be any serious obstacle to the plants being used in lines or masses; while when grown in isolated places in borders and on rockeries the variations are acceptable rather than otherwise. The plants cannot be raised too early now. Sow the seed in boxes, cover with a square of glass, place in heat, and keep the soil constantly moist. When the seedlings are large enough transplant them 6 inches apart in rows 1 foot asunder in good soil, and a sheltered position; and with care in watering as needed, stirring the soil frequently, good plants will be had in October for placing where they are to flower.

Tuberose Culture (Old Subscriber).—You ask for "a simple system" of growing these fragrant flowers. The following will probably be of assistance to you. The bulbs may be flowered either singly in a 5-inch pot, or three can be placed in a 6-inch. A compost consisting of three parts fibrous loam to one each of good leaf soil and decayed manure passed through a coarse riddle, with a little coarse sand, suits them well. Pot rather firmly, the bulbs being about three parts buried, but if the soil is moderately moist do not give any water. Set the pots in a frame and heavily cover with cocoa-nut fibre refuse, or if a frame cannot be spared put them under a greenhouse stage where little or no drip will reach them, and cover thickly as previously advised. When rooting freely and top growth has commenced they must be at once uncovered and gradually exposed to the full light. Early started bulbs will flower in an ordinary greenhouse during the summer, and even in the open air, but later they will require to be gently forced. The flower stems ought to be kept well secured to stakes, and liquid manure may be freely given after the pots are well filled with roots. A few may fail to throw up flower stems, but the majority will give one good spike, after which they are of no further value, and should be thrown away. Red spider is the worst enemy with which Tuberoles have to contend, but this can easily be kept down with the syringe, and a puff of tobacco powder followed by the syringe will prove efficacious against green and black fly.

Diseased Peaches (H. W.).—The fruit has arrived at the stage immediately preceding stoning, when it is liable to the "second dropping," for there are four periods at which the Peach and Nectarine are subject to cast their crops, as is well known to experienced cultivators—namely (1) shortly after the fruit has set—imperfect fertilisation; (2) just before commencing the stoning process—defective ovule formation; (3) near the close of stoning—unmineralised stone formation, commonly due to excess of nitrogenic nutrition, or imperfect elaboration and assimilation on the part of the plant; (4) lack of nourishment just when the fruit commences ripening—overcropping, excessive evaporation, or insufficient supplies of water. The fruit in your case represents the second of the stages above mentioned. Two of the specimens—one oval in form and relatively large, the other rounded in shape and comparatively small—were carefully examined. Singularly both contained two ovules, and in the pointed fruit one of these was brown and the embryo dead, while in the blunt fruit both the ovules had sound embryos. One of the fruits we suspect had fallen, and the other been taken off the tree by hand. On the outside and at the base of the larger and conical fruit was a depressed spot—indeed, a hole, and in that cavity a number of abnormal hairs, whereon were situated oval eggs—*Phytoptus persicae*, the Peach tree gall mite, "miller" of France, and known since 1851 (Ann. Soc. Ent. France). This had no connection whatever with the dead ovule. In the ovule were mycelial hyphae of the stone fruit brown rot fungus (*Monilia fructigena*), and it had entered by the nipple—stigma, or style of the blossom. This fungus is a common cause of gumming in stone fruits, the branches as well as the young shoots dying off suddenly and without apparent cause, and frequently of the flowers not setting. It always affects sappy trees most, hence trees subject to it produce wood spasmodically, for the parasite exploits the host plant, even when weakly, in order to provide itself with abundance of food. We found the most relief to accrue from lifting the trees, the effects of which are seen in wood which is not liable to favour the parasite. It is doubtful if any outward application has any deterrent effect after the flowering is past; besides, the use of sulphate of copper is not advisable, as Peaches hold the carbonated copper, and may not be safe. We have found, however, that spraying with sulphate of copper—1 oz. to $1\frac{1}{2}$ gallon of water—just before the blossom buds commence swelling has a good effect, and can then do no harm. The thing, nevertheless, is to get the trees into sound health, and to that end we advise lifting at the proper time.

Manures and Their Application (W. T.).—You ask for a cheap work on this important subject. We do not know of any manual conveying so much information relative to the different kinds of manures, their nature and uses, for so small an outlay of money as you can obtain by sending 6d. in stamps to Mr. W. Dyke, Cranbourne Nursery, St. Margarets, Ware, Herts. The overwhelming majority of young gardeners might study it with advantage, and many of their seniors too. It contains thirty-one closely printed pages in a paper cover.

Vines Infested with Thrips (Tyro).—To destroy the thrips, with which the specimen you send is infested, you must fumigate with good tobacco paper, taking care to have the foliage dry, and not to give an overdose. The great evil of thrips is that fumigations, even nicotine vapourisations, for their extirpation need to be repeated at intervals of a few days, because the first application only destroys the insects then existing. The Vines in the course of a week or ten days may be again infested with thrips simply because another generation has appeared. Repeat the fumigation at not more distant intervals than a week for a few times, but avoid it while the Vines are in flower.

Vines after Dressing with Petroleum (S. R.).—The picture you draw of the Vines is a very accurate one, and shows the importance of not taking advice from other than practical and experienced cultivators. We have often drawn attention to the dangerous practice of using petroleum on Vines, the oil does not mix with water, and has often done irreparable injury. The man who recommends the use of pure paraffin to Vines is a dangerous adviser. As for red spider, it remains on Vines from year to year, and no matter how properly ventilated and cared for the house may be, Vines are subject to it without special care. It delights in a dry atmosphere, and attacks Vines badly nourished at the roots. Yes, Alicante is more robust than Black Hamburgs and most white Grapes, and that suffices to account for the difference in the injury inflicted. There is no question that the petroleum combined with the severe peeling did the mischief. Only the soluble form should be used, even as a winter dressing for destroying the hibernating red spider or eggs. Several people record having seen spiders hatch from the red eggs in spring, but red spider eggs are white, and the "insect" does not hibernate in them.

Manuring Vines (A. M.).—The "exact quantity of human excrement required for each Vine of one rod" cannot well be stated, as you do not mention the extent of the rod or border space. If the Vine has as much rooting area as the amount of rod space you may put on an inch thickness of ordinary earth-closet manure in a crumbling condition, and point into the soil after the Vines have been pruned, afterwards dressing with one of the advertised Vine manures at the rate of 4 czs. per square yard before the Vines come into leaf, or when swelling their buds, pointing in lightly, or washing in moderately after the soil has been brought into a proper state of moisture. Repeat when the fruit has set, and again as soon as the stoning is completed. These three dressings, amounting to three-quarters pound per square yard of substantial Vine food, with the night-soil dressing, will give you splendid results, at least it has a market grower, whose produce in bulk and quality it would be difficult to excel. As for liquid-manure water we do not see that you will want much of it, but if you consider the Vines need more vigour you may dissolve a quarter ounce to a gallon of water of sulphate of ammonia if the soil be rather strong, nitrate of soda if the border be of a light or calcareous nature. This may commence after the Vines come into leaf, continuing as the border needs supplies of water until the Grapes change colour for ripening, when discontinue its use. You must exercise your own judgment as to when the border needs watering, taking care not to make the soil sodden, and thus inducing shanking, whilst not allowing the Vines to be distressed through lack of due supplies.

Utilising the Refuse of a Cigar Factory for Fumigating (W. T.).—The fumigating sheets in general use are prepared in various ways, the process of which is only known to the proprietors. We have known the "refuse"—an exceedingly valuable material, when care is taken to keep it perfectly free from sulphur, for fumigating fruit and plant houses—utilised in the following ways:—1. Dissolve a tablespoonful of saltpetre in a pint of water. Take pieces of the coarsest brown paper, 10 inches long and 6 inches wide, and when the saltpetre is dissolved steep thoroughly in the solution, then dry them, and keep till wanted. When required to fumigate, roll each piece of prepared paper lengthwise into a pipe, leaving the hollow not less than half-inch in diameter, which fill with the cigar refuse, and twist one end of the pastille. This end may be inserted in flower pots filled with soil, sticking the pastille erectly; light the other end, and it will burn out gradually. With a number of these disposed through the house according to size fumigation can be very effectively carried out without being subjected to the smoke beyond the time taken in lighting. 2. Prepare sheets of coarse brown paper as per 1, and when dry brush them on one side with a solution of gum arabic, a tablespoonful to 1 pint of water, dusting on the damp surface as much cigar refuse as will adhere or cover it. Allow to dry; then dress the other side in a similar manner, drying and keeping for use as required. These sheets are simply placed on or in empty flower pots and left to smudge or burn out. In both cases a certain degree of moisture is necessary to secure steady burning, the comparatively slower the better. Perhaps you may be able to improve upon the modes of preparation given, or some of our correspondents may know of better. We may say that 1 oz. of the cigar refuse to half a gallon of boiling water in a vessel covered up until cooled makes excellent tobacco water, and if then strained through muslin is fit for

spraying or syringing on plants infested with aphides, thrips, and other pests, it being still the best mode of cleansing fruit trees from "flies" and "grubs" of all kinds.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (Devonian).—The specimen you send is of *Cerasus virginiana*, of which you will find some interesting particulars with an illustration on page 459. (W. S.).—*Orchis mascula*. (Wilts).—*Geum rivale*. (C. G. M.).—1, *Cerasus* (*Prunus*) *Padus*; 2, *C. serotina*. (F. V.).—1, *Campanula garganica*; 2, *Weigela rosea*; 3, *Viburnum Opulus*; 4, dead. The flowers are of *Streptosolon Jamesoni*, an easily cultivated greenhouse plant, which well grown and carefully trained forms a very beautiful object. (A. M.).—*Mackaya bella*.

ON SPOILING GOOD LAND.

NOT intentionally, by any means; ignorance has more to answer for than pure malice. There are very few malicious people about, but a good many ignorant ones, and endowed with that most hopeless form of ignorance, overwhelming conceit; a conceit that makes them both deafer and blinder than the nations who sat in darkness, of whom the prophet spoke.

The worst of it is that some of the good land has been spoiled at great expense. The money has been deliberately thrown away—buried fathoms deep. Some startling facts have lately been presented to our notice by the Rev. E. Adrian Woodruffe-Peacock, F.L.S., F.G.S., a Lincolnshire vicar, a man who thoroughly understands what he is talking of. He is speaking of drainage on heavy low-lying soils. He is a man of great observation, and he throws a light on several things that have puzzled us for a long time. We heard the same questions discussed years ago in our childhood's home, where much money was annually expended in draining and re-draining the strongest of Holderness clays.

Within the last twenty years a material change has come over our farming, and we no longer find the fine Wheat crops we used to know grown on strong land. The crop now is not worth the labour of production, and therefore the golden grain has given place to pasture land.

A generation ago draining on the whole was neglected, then came a time of reaction, and, as is generally the case, the new converts were ardent, zeal not being tempered with discretion, and the consequence has been that in dry times the land is perfectly denuded of every drop of moisture. The cattle have no drinking places, and the dykes that stand instead of fences are simply useless.

Mr. Peacock says:—"Many of our unyielding clays are as good as impervious to water a little below the soil limit. In such stiff clays the pipes should be laid as near the surface as is consistent with avoiding agricultural operations, and with retaining their proper position under the pressure of cartage."

Some of our less impervious clays which were drained in bygone years for Wheat growing are much too deeply sapped for grass in a dry season. Wheat has a water root, which will go down till it reaches moisture; grass not having that natural advantage dries out and perishes. It is difficult to bring that water back again, and we have had these last dry seasons to pay the price of our forefathers over zealous draining. The price has been paid twice.

Has anyone noticed what a shrinkage there is when peat land has been drained? Whittlesea, Mere sank 9 inches per annum for the first ten years after it was drained. On such soil pipes are practically useless, the area is elastic and shrinking, and the pipes by pressure from above soon become unlevel, and get choked. Tiles and flats obviate this difficulty, the tiles meeting in the middle of a flat, and the flats in the middle of a tile. The pressure from above on a tile carries the junction of two flats with it; the tiles at either side on the other ends of the flats keep them in their places.

On grass land there should be no stagnant water in the surface soil, and just below heat, air, and rain will enter freely. "Drain too much, so as to destroy the capillary from the water table supplying the loss of moisture from evaporation, the heat produces drought, and the air, finding free access, but lacking the moisture, which is its brother workman, proves a curse rather than a blessing by draining the soil still further of its water, as tens of thousands of acres of valuable pasture and meadow demonstrate to the eye that can see at this moment."

But excessive draining is not the only way of spoiling good land. To anyone who has much acquaintance with farm leases or agreements we need not speak of the rigid laws therein laid down. In most, except perhaps a few very modern ones, the farmer is tied hand and foot. No variation in season, no fluctuation in price, no land sickness are allowed for. Who has not heard of Clover sickness and finger and toe in Turnips? Whereas a little judicious cross-cropping would put money into the farmer's pocket and heart into the land.

We know farms where a farmer daring to grow Potatoes would, if leaving, be mulct to the extent of £5 per acre for all his Potatoes, although at the same time no one could deny the magnificence of the following Wheat crop or the garden-like cleanliness of the soil. There was another little fad which at one time proved a most useless and expensive experiment—we refer to steam cultivation. If Mr. Peacock speaks of thousands of acres of good pasture wasted by injudicious draining, what of thousands of acres of good arable land utterly ruined by the bringing up of bad useless subsoil? Land does not get over treatment of that sort for one generation, and nothing will make stiff tenacious clay change from the character of bullock's liver in consistency as well as colour.

WORK ON THE HOME FARM.

Instead of becoming warmer the weather has been colder and colder every day. It was cold enough when the wind was in the north-west and north, but now there is a spice of east in it the temperature is more like March than May. Several frosts have been noted in the early mornings, but not so severe as is reported from other districts. Rain is beginning to be seriously wanted; there is no absolute drought, and there is plenty of moisture beneath the surface, but the frosts and dry cutting winds have had a bad effect on young vegetation, and rain is the only antidote. Let us hope when it comes we may have more genial weather with it.

The later Wheats have again shown improvement, but the earlier ones have still further gone back. Barley and Oats on sound land still look fairly well; on the other hand many fields show patches of yellow, indicating places where either the subsoil is weak or the drainage deficient.

Thousand-heads are up, and look well; Mangold comes up slowly, and is almost as well under ground as the weather is now; early Swedes and Turnips are all in, but not up yet. We are only waiting for a nice rain to mellow the soil and improve the tilth, and we shall at once have in the main bulk of the Turnip crop.

Though it has been a bad time for growing crops, it has been capital for dealing with weeds and twitch, and cleaning of fallows is now quite completed. It is almost a record, for we can with difficulty remember such an early and satisfactory finish. We, whilst waiting for rain, can afford to give the horses a rest, and send all hands to the hoe. Wheat has been looked over, and has not furnished an arduous task.

Barley and Oats are rather full of thistles, worse than we had thought, but are being rapidly run over. Potato weeding is the next operation. The tubers have been slow in sending up the young shoots (fortunately so), and very few are appearing yet, so we have to wait as cleaning cannot be done with safety until nearly all are showing. Live stock are looking fairly well on bare pastures.

Journal of Horticulture.

THURSDAY, JUNE 3, 1897.

OPEN AIR TOMATOES.

TOMATOES having succeeded so well in the open last season, they will be grown in still greater numbers this summer. Plants I mean, not fruit, as it is not to be expected that such exceptionally heavy crops, good in quality as well as in quantity, will be obtained oftener than once in three seasons. The Tomato is an American fruit, and we had an American summer in 1896. Complete failures there need never be. What I mean to say is, that the southern cultivator is to blame if he fail to gather enough ripe fruit in a bad season to pay for the trouble of growing, and the small unripe fruit which can be turned to account in various ways represents the profit.

Open air culture of the Tomato, as it happens, does not invariably partake of the character of a lottery as sometimes asserted. A grower near Bexley Heath, in Kent, devotes about 5 acres of ground to Tomatoes, commencing, if I remember rightly, in 1891. In that season enough fruit was marketed to pay for the ground, and that after paying all working expenses. When asked how many failures he has had since, the reply was, Not one. He had not had a single bad year out of the five, and the crop of 1896, as I saw, promised to be a record one. Amateurs, and not a few professional gardeners, are under the impression that Tomatoes can only be successfully grown under glass, and against sunny walls, fences, and screens in the open. The thousands of plants annually put out at the Bexley Heath farm alluded to are sheltered by a wood on the north and north-east only. I, too, have grown thousands of plants quite in the open for the last three seasons, and all the shelter these had was afforded by rows of tall Peas and Runner Beans.

It must not be thought that I attach no great value to the warmth and shelter afforded by a sunny wall or fence. On the contrary, I would, where possible, utilise every blank space on sunny walls for Tomatoes, but such luxuries are not generally available, especially for the production of tons of fruit. My point is that they can be dispensed with. The amateur may grow his score or so of plants, the professional gardener his hundreds, and the market grower his

thousands quite in the open. Not necessarily in the hottest and best sites, or, say, borders in front of walls facing south, but equally as well in a sunny quarter, sloping to the south for choice. My ground in Somerset slopes nowhere in particular, but the soil is moderately warm and free working. The Bexley Heath ground appeared to be composed largely of pebbles, and thanks to these stones the plants do not suffer from drought so quickly as mine do.

Preparation of the ground merits a separate paragraph, not because there is any important secret to be disclosed, but merely because it is simplicity itself compared with orthodox instructions as set forth by old masters. What I advocate is that Tomatoes require much the same treatment, as far as preparation of the ground is concerned, as Potatoes. One, two, or three shovelfuls of fresh fibrous loam with a sprinkling of bonemeal added may answer well when only a dozen or two plants are grown, but is out of the question in the majority of cases. Dig in half-decayed mixed farmyard or good horse stable manure freely and deeply, doing this if the soil is of a clayey nature early enough in the year for it to become well pulverised before May, and that ought to be sufficient preparation. If the manure is the usual old, quite decayed hotbed stuff common to so many gardens, then I would add a dressing of Thomson's, Albert's, Clay's, or other maker's manures at planting time, stirring, not digging this in.

Why I suggest that the ground be got into a free working condition before May is because this affords a good opportunity for double or intercropping. My plan is to plant early Potatoes in long rows, 3 feet apart, and midway between these the Tomato plants are put out in due course. We are later than usual in planting the Potatoes—luckily so as it happens. If planted during the first three weeks in April they would most probably have "come up" by May 11th, in which case all not covered would have been blackened by a severe frost. Late planted as they are they will not interfere with the work of planting or future progress of the Tomatoes, and both crops will be all the better for the ample room allowed them.

What and when to plant have next to be discussed. The rage for handsome, smooth, round fruit has seriously militated against the success of many growers of Tomatoes in the open. We all like them; but the more shrewd market grower prefers a certainty, even if accompanied by comparatively low prices, to an uncertainty with a gain of one penny per pound for what produce may be sold. I cannot name a single smooth round sort that does not crack badly in showery weather. They are as bad as Gooseberries and Cherries in this respect, and cracked fruits are not wanted.

There are several corrugated varieties available that are not so coarsely ribbed as the old Large Red, and of these the best are Early Ruby, Laxton's Prolific, Earliest of All, and Laxton's Open Air. The old Keye's Prolific is also reliable, and heavy cropping. I have had Ruby fruiting in masses from the ground to a height of 30 inches, and at Mr. Hammond's fruit farm near Brentwood, Essex, I saw last season racemes of fruit on Laxton's Prolific fully 18 inches long. This season I am only growing Ruby and Laxton's Prolific extensively, and in neither case will many really coarse fruit be seen on the plants. It is true the first large flowers on Ruby would, if left alone, be followed by large, unshapely fruit; but these are invariably pinched off early, the rest of the crop benefiting accordingly. There may be a little cracking of fruit going on whenever the weather is showery, but it will be trifling compared with what would have happened had smooth round fruited varieties been grown.

Large plants in 6-inch or larger pots in flower, or with fruit already set upon them, are things of the past in my case, and will never again be recommended for planting out by me. At the present time we are discarding strong plants in 3-inch pots, or such as might be given a shift into larger sizes at once, in favour of others only just recently placed singly in 2½-inch pots. By the end of May these will be about 5 inches high, strong, and well

rooted. At this stage and size they can be rapidly planted out, and are in just the right condition for becoming quickly established in the surrounding soil. This applies to any planted against walls as well as in the open. When turned out of larger pots much more water is required at the outset, and if this is not applied what becomes of the first bunch of flowers? My small plants are growing strongly before the first flowers show, with the result that these do not drop off prematurely, but are followed by fruit. If the weather is favourable our planting will be done during the last week in May, but should the nights keep cold and frosts be imminent, the planting will be deferred another week. The Bexley Heath grower is sometimes a fortnight earlier in commencing planting, and once completed his five acres early in May. It is to be hoped he has not been quite so venturesome this season.

When grown quite in the open Tomato plants must be kept fastened to either stout stakes or bamboos secured to a single wire. I find the latter plan the cheaper, and it answers admirably. Light 3 feet bamboos will be thrust into the ground at a distance of 15 inches apart in the rows, and fastened near the top to a light wire strained to stout stakes at distances of about 20 feet apart. This will be done in advance of planting. If only a few were grown inverted flower pots or other form of protection could be used if necessary, but our plants will have to rough it. According as they grow all are secured to the bamboos. Not a side shoot is allowed to develop, or at any rate not if it can be helped, and if need be the plants are topped when nearing the wire.

We sometimes see it stated that Tomatoes in the open ought not to be watered. I tried dispensing with the hose and watering-pot, and also with the usual mulching of manure, but it would not work. Last season only the well mulched, heavily watered rows produced remunerative crops. Those treated to lime from chalk, those not mulched, and those that did not receive enough water collapsed wholesale, apparently from the drooping disease. This season they will be grown as strongly as possible.—W. IGGULDEN.

HARDY FLOWER NOTES.

SPENSER tells us that "May is the fairest maid on ground," and it is difficult when in the full enjoyment of the sweet flowers of early summer to question his words. True, up to the time of writing, this year the fair maid has been in hoyden humour and careless of her floral garlands. Her breath has not been sweet and balmy or her movements gentle and graceful. She has been rough in her ways, and has tossed about the tender flowers as worthless things fit only to be spurned and despised. Yet with all how delightful the time! Tree and bush, hedgerow and meadow of the brightest and freshest green, save where the flowering trees and shrubs have essayed—and not in vain—to outshine the others clothed only in their exquisite verdure. Orchards are feasts for the eye, as hereafter they will yield to the palate its share of the bounties of the year. In gardens where the fruit trees are to be found beside the flowers there is friendly rivalry as to which will please the more. We know of many such gardens full of interest from month to month.

In some a Clematis or other slender climbing plant yearly finds its needed support among the branches of the trees, and adds beauty to the garden. Perhaps there may be a few Apples or Pears less, but those which do grow give a finish to the picture in autumn, when Sunflowers glow in the border and Hollyhocks rear their spires among. One cannot say so much of every garden, but in some old places what Herrick calls

"The blushing Apple, bashful Pear,
And shame-faced Plum"

never look out of place beside the flowers, even when the exquisite bloom of a Clematis looks out coquettishly from among the fruit.

These thoughts arise as one looks upon a fine plant of *Trillium grandiflorum* which has for some days been delighting us in its moist, half-shady nook of the rock garden. Beautiful as it is, large as are its flowers, it is less beautiful and its flowers are smaller than those of the parent plant, which, in another garden, flourishes beneath the branches of an Apple tree. Those who see a small

plant of this Trinity Flower cannot realise the effect of a mass of purest white rising among the fresh green leaves, strong and vigorous, unlike the plants we so often see.

By the little Water Lily pool the double *Caltha palustris* is thickly studded with its large golden buttons. It is more happy there than in the dry borders, and is evidently in luxuriant health where it grows in the wet soil and with its roots running down into the water. Comparatively common though it is, this old double Marsh Marigold shows how fine a plant becomes when it receives congenial fare. On another side the sister *Caltha leptosepala* is happy too, but its white flowers suffer in comparison with those of the commoner species. *C. leptosepala* has been tried in several positions, but with its roots in the water it is evidently more happy here than anywhere else. It does not cover itself so freely with flowers as *C. palustris* fl.-pl., but produces them more sparsely for a long time in succession. It is a native of North-West America, whence it was introduced in 1827. The pure white flowers are produced from one to two (but generally one) on rather long peduncles, and are here about three-quarters of an inch across. The glossy green leaves are radical, cordate, and generally entire round the edges, but are occasionally crenate. It is said to be described and figured in Hooker's "Flora Boreali-americana," vol. i., plate 10. As already said, it is evidently happier with its roots in the water than anywhere else, but does fairly well in a half shady moist nook in the rock garden also. It is certainly not a showy or effective plant, but gives a pleasing variety where there is room for a large collection. The English name of Slender-sepaled Marsh Marigold is not particularly attractive, although somewhat alliterative.

The quaint-looking *Epimediums* generally attract admiration by reason of their singular-looking flowers and their slender habit, combined with the exquisite tints assumed by the leaves at different seasons. The European *E. alpinum* is attractive, and, although naturalised in Britain, is worthy of a place in many gardens. The Japanese *E. Muschianum* is at present very pleasing close to the edge of a narrow border. *Mussche's Barrenwort* is not so fine as *E. macranthum*, perhaps the finest of the genus, but is very suitable for such a position as that in which it is grown here or for the rock garden. The little flowers are described by some as dull white, but the qualification of "dull" does a little injustice to the blooms. They are not of the purest white, but do not look "dull white" when seen on the plant with its fresh-looking leaves formed of nine little cordate-ovate leaflets. It came from Japan about sixty years ago, and a figure of it will be found in the "Botanical Magazine," table 3745.

Near at hand, but presenting a great contrast to the unassuming beauty of the Barrenworts, is a clump of the old Tulip known as Golden Eagle. There has been of late a general effort to ascertain the correct names of some of these old garden Tulips now having their renaissance. This variety has pretty well proved its right to the name, which has also been applied to another showy one, the correct name of which is Golden Crown. The latter is at first entirely pure yellow, and then becomes edged with red, which gradually broadens as the flowers reach and pass their perfect stage. Golden Eagle, on the contrary, retains its bright yellow—perhaps a little deeper than that of Golden Crown—to the end, and is also less pointed in the segments, and with me is hardly so tall. I believe both are referred to *T. Billietiana*, which appears to be rather a variable species, and comparison certainly gives strength to this view. Many persons, of whom I am one, have been misinformed about which was the true Golden Eagle, so that others may be the better of the present remarks. Both are effective Tulips among herbaceous plants, where their flowers are seen to great advantage.

Soon the Narcissi will be gone for the year, and before they depart one would like to say a word or two about the smallest and neatest of the Burbidgei group. Possibly we have too many varieties among these hybrid Narcissi, and the value of some is reduced here by their flowering, not before but contemporaneously with *N. poeticus ornatus*. There are, however, some very beautiful flowers among these, and admirers of the Narcissus are pleased that one group at least bears the name of the talented curator of Trinity College Gardens, who has done and is doing so much to increase the knowledge of, and love for the Daffodil. In gathering together my small collection of this group I have included a good proportion of those with yellow or primrose coloured perianths to form a pleasing variety to the early flowers of the poeticus group. Among these is the one referred to, Little Dirk, a charming little flower of sturdy habit and good substance, with pleasing primrose perianth, and a small cup with a bright orange-scarlet edge. Those who like large "floppy" flowers had better leave it alone, but the many who admire small blooms of perfect form might with advantage add *N. Burbidgei* Little Dirk

to their gardens. Too soon the Poets' Daffodils will have departed to join the others in their summer sleep. Meanwhile we look on them admiringly among the throng of other flowers which have welcomed the coming of summer, and of which there is no space to tell.—S. ARNOTT.

IN SEARCH OF SUNSHINE.

THE LEAFY GROVES OF SANS SOUCI.

WHEN the sun is glinting the young leaves in the magnificent avenue of the Unter den Linden, when its hot rays stream from the white columns of the Brandenburger Thor, then does young Germany wend its way to Potsdam. Make no charge of exaggeration regarding the word "hot." It was the 28th of April, but a sun of fine midsummer quality beat down on the queenly capital of Germania Unita. The white-hatted cabbies (some of whom have heads too large for their hats, and others hats too large for their heads) wagged placid slumber; the café proprietors took out their shop fronts bodily, and tossed them no one knows where; and dewy globules sparkled on the duel-scars of the long-legged officers. Happy those whose way took them through the green and shadowed grove of Berlin's great road to the home of her warrior kings.

I had made no particular noise about my intention to visit Sans Souci, nevertheless I found a considerable crowd at the station. My gratification at this fact was modified by the discovery that special fast trains were running, and this afforded another explanation of the presence of so many. It is just half an hour's run from the important station called the Potsdamer Bahnhof, and here let me express a sense of what is due to those authorities who have made Berlin what Bismarck made Germany—great, imperial, and impressive. The plan of the town is such as to make a candid cockney weep for his poor, tortuous muddle of a London. Charles Dickens secured immortality for Mr. Weller the younger when he gifted him with a knowledge of the dear, dirty, old metropolis that was "extensive and peculiar;" but a German Dickens could not make a German Sam by a similar stroke of genius. The great streets of Berlin run in a vast series of parallelograms, and anyone with ordinary intelligence can swiftly learn to make his way from one part to another without rambling into blind alleys, or taking short cuts which add to the distance. Moreover, the local railways put plans of their system in the compartments. There is a Ringbahn or circle railway in addition to the great State lines, and by a little study of the plan the whole town can be traversed without troubling to worry people with questions in a language you only half understand.

Berlin does not plant trees in all its streets, but in addition to the wonderful Linden avenue, which is some 70 yards wide, and is a Piccadilly, Rotten Row, and Clapham Road (with the tram lines) all in one, there are others, such as the Königgrätzerstrasse, that are tree-lined. The latter skirts the large park known as the Thiergarten, and leads direct to the station which is in special connection with Potsdam. There are dozens of streets wider, finer, and infinitely cleaner than Regent Street. All the buildings are lofty and massive. They are not of solid stone, although they look like it; but the bricks are faced with what may be termed plates or moulds of a white composition, by the universal use of which a striking and bold uniformity is secured throughout the whole of the City. It would be of no use to follow the same plan in London unless a facing compound could be employed that would defy the persistent rain of powdery filth that makes us so sombre and gloomy. We could use more trees, though, especially in the making of new thoroughfares.

There was to be a horticultural party to Potsdam on the Saturday following the opening of the great exhibition, but I had to be elsewhere on that day, and so I went earlier alone. In this, had any formidable obstacle loomed up, I could have found encouragement in the example of Smollett, who liked foreign travel, and liked to go by himself. I have referred to the large number of others who went also. I was a little surprised to see them all take to their heels as soon as they got out of the train, but the explanation came when I turned a corner, for there was a pleasant stream, and a pleasant bier-garten beside it and a pleasant steamer on it. I had no idea where the latter went save a vague speculation that it might be to Sans Souci by a back water way; but I might have boarded it had there been a square inch of surface left. The people, however, were packed like American Apples in a barrel, and were just about as plump and rosy. It is not often a German beer-garden is seen empty on a hot day, but

the world and his wife had flocked on to that vessel and packed it to the tip of the funnel.

The old castle of Sans Souci is about two miles from Potsdam railway station. It can be reached by a tram, but I preferred to walk. A gentleman awaited me at the gates. He might have been taken for a delegate from the authorities, but the air of rapacity lurking beneath the mask of smiles upon his face, not less than his wild flow of conversation, proclaimed him for what he was. He begged to offer his services to the noble Herr as a guide. The noble Herr vanquished him by a slight variation of Curran's method with the fish wife, informing him (in English) that if he could promptly lead the way to the beds of *Rhododendron ponticum* he should be engaged regardless of expense. I may remark that I exercised a certain amount of caution in entering all gateways. The military element is all-powerful in Germany, and Potsdam itself is a town of soldiers. My care arose from the fact that I have understood the plan adopted is to shoot first and argue afterwards—a system which did not commend itself to me. However, there was hardly a sentry to be seen, and all was peace.

The grounds are very extensive, and are attractive in the height of their spring beauty. I entered them by what I believe is known as the Obelisk Gate; anyway, there is a hieroglyphic erection near which bears so striking a resemblance to Cleopatra's Needle, that one might imagine it had been transported there from the Thames Embankment and spring cleaned. A long walk leads from this point along the front of the castle, past the circular basin which contains the famous Sans Souci goldfish. I am not a pisciculturist, but I could not refrain from pausing and admiring the fish. They are veritable monsters, nearly as big as trout, and coloured like a Poinsettia. The veterans looked extremely sprightly and cheerful. They have lived out great events, some of them, and have whisked lively tails while world-moving events, big with the fate of nations, have been talked of near by, but they are youthful and vigorous still. I tempted them with a fragment of antiquated English cake, extracted in a mummy-like state from the corner of a pocket, and national pride did not prevent their making a rush for it. I fancy the winner was a little sobered, though, by the time he had disposed of it. He was a hale old fellow, but short, perhaps, of teeth.

One of the greatest horticultural sights of Sans Souci is the series of terrace houses flanking the sides of the long flights of steps leading up to the centre of the Castle. The latter, it must be explained, is built on a hill, the face of which has been cut out into a series of six terraces, each about 90 feet wide. They are terraces, be it understood, and not banks. Each has a perpendicular face about 12 feet high, and the whole has been covered with glass, so as to form long ranges of Peach houses and the like. They are wide enough not only for the trained trees on the walls, which must give an enormous quantity of fruit, but also for one line of orchard-house trees, such as Pears, in large pots. The latter were smothered in bloom, and the whole presented a very striking spectacle. In front of the houses, or rather cases, on the bottom terrace were planted, at a distance of a few feet, Vines so trained as to stretch across from their uprights to the front of the Peach range. Above there were miles of espaliers, and even such things as trained Currants and beds of Strawberries, so that there is a complete fruit garden.

The remaining space on the terraces is planted with flowers. There are extensive beds of Roses, both standards and dwarfs, pruned, it was noticeable, on lines approved in England. They alone must present a magnificent spectacle when they are at their best. The spring flowers were mostly bulbs and Pansies. In the way of shrubs Forsythias and Magnolias held sway. The former reminded me of modest Sittingbourne, the latter of stately Belvoir. But the beautiful plants which Mr. Divers has to show his visitors are on the Castle walls, whereas those at Sans Souci grow in the open. They are objects of great beauty, being full of noble flowers, and the varieties are not limited to one. There is no thick planting. We have a monopoly of that sort of thing. Many people would think the continentals go to the other extreme, and plant as much too thinly as we do too thickly, but as a matter of fact it is simply a case of fundamental differences in peoples showing themselves. We are secretive, and like to shut ourselves in, aiming at total privacy. The Dutchman and the German are open, expansive, and perhaps a little vain, liking for everything they have to be seen.

A serious disadvantage presented itself when I wanted to get among the houses in the parts closed to the general public. I was

alone, and unable to make my wants understood. I thought it possible that if I were able to explain that I was not a casual but a horticulturist (in however humble a way), and that I represented an English horticultural journal, an exception might have been made in my favour. Unfortunately I did not drop across anybody who understood my pure and academic German, as culled from Otto and other authorities, and my stock of colloquialisms was too short. I have no doubt that the great and gifted Kaiser possesses ranges of vineries and Peach houses; I have likewise no doubt that they are worthy of a few remarks, but I did not see them, and I therefore contented myself with a gaze at the large orangery, then went my way.

I have spoken about the great tree-lined roads of Berlin. I found another of them when I returned from Potsdam and set out to visit the Royal Botanic Gardens. Its name is the Potsdamerstrasse. This magnificent thoroughfare almost equals the pride of Berlin—the marvellous Unter den Linden. It is not so wide, and it lacks the beautiful electric avenue in the centre, but it is of great length and is full of splendid buildings. The Botanic Gardens are open from ten o'clock, I believe; anyway the gates were open when we arrived a few minutes past. No doubt if Mr. John Burns sees this he will utilise it the next time he agitates in the House for the earlier opening of Kew. But fairness demands that the differences between the two places should be pointed out. I would by no means disparage the German Garden, for it is well managed, and does useful work. Moreover, I hold it a very cheap form of amusement to glorify one's own country at the expense of others. Still Berlin is not Kew, and the Germans themselves would be the first to acknowledge it. There is, in fact, a project now afoot for shifting the whole establishment a little further towards the country, greatly enlarging it and improving it in the process. The matter is at present before Parliament, and an early settlement is expected.

I was fortunate enough to have a short interview with the Director, Professor Engler, and also with the Curator, Herr Perring. The accomplished Director is now busy on the conclusion of his great work, *Natürliche Pflanzenfamilie*. He speaks English, and was kind and cordial to a degree. It would be easy to fill a page with a description of the specimens in the museum, but I will content myself with a word or two about the gardens themselves. They comprise many departments. For instance, there is the purely scientific section, which, with its maximum of huge labels and minimum of growth, is known to the irreverent as the cemetery, from which it would appear that feeble wit is not limited to one island. There is, too, the geographical department, in which the plants are grouped according to their habitats, such as those of the German mountains, the Central Alps, the Caucasians, and others. One feature of much interest is the series of frame enclosures, containing (chiefly) bulbous plants. Amongst these were noticeable several Irises, such as *furcata*, *notha*, *Lorteti*, and *Mariæ*; a charming Alpine form of Tulip, *T. pulchella*, very dwarf and with flowers of a vivid carmine; many *Fritillarias*; *Anemone fulgens* var. *purpurea violacea*; *Leontice altaica*; *Ranunculus rupestris*, and a few *Crocus* species. Here and there were groups of shrubs, the brightest of which were the quartette of *Prunus*—*triloba*, *persica*, *amygdalus*, and *nana*. The last named was not the least attractive. It is a true dwarf, wreathed in charming bright pink flowers, and is so useful and beautiful that it is worthy of extensive planting.

The glass department is fairly extensive, but more room and a newer type of house are wanted. The large Palm house contains a number of specimens; indeed, the first to meet the eye on entering is a *Livistona oliviformis* 30 to 40 feet high. There are, too, giant Musas, a fine *Carolinia insignis*, *Sabal Blackburniana* in a tub 5 feet across, and many other notable plants. Orchids are few. I observed *Odontoglossum Uro-Skinneri*, *Phajus Wallichii*, *Epidendrum ellipticum*, and *Cattleya intermedia* flowering in one house. The collection of *Nepenthes* is excellent, and Ferns are very well represented; but the most notable plant in the fernery was the graceful *Asparagus Sprengeri*. It is a most free and graceful plant, well adapted for table decoration. Hardwooded plants are excellently grown, and the collection is representative. The general impression of my visit was that the German botanists make very good use of very limited conveniences. When they get their new establishment they will be treading our economic heels off more determinedly than ever. Alert, energetic, neither too proud to imitate nor too independent to display pliability when their customers' wishes call for it, they are, as traders, a people to reckon with. England must not sleep on her mighty past.—W. PEA.

STYLOPHORUM DIPHYLLUM.

THE Celandine Poppy (fig. 93), though it has been in cultivation in this country for about forty years, is still an uncommon plant in our gardens. It is a hardy herb with a perennial rootstock, and has a considerable resemblance to *Chelidonium majus*, to which, however, it is much superior. It attains a height of 1 foot or 18 inches. The foliage is deeply pinnatifid, soft in texture, greyish-green above, and glaucous beneath. The flowers are freely produced in May and June; they are about 2 inches in diameter, and of a deep yellow colour. The plant is quite hardy, and will thrive in any light garden soil. It is easily raised from seed, and can be increased by division of the rootstock. It is a native of North-west America. *S. japonicum*, the only other species in cultivation, is sometimes confounded with *S. diphylum*, but it is quite distinct. It is a native of Mandschuria and Japan.

PRECEPT AND PRACTICE.

PICTURESQUE GARDENING—WATER.

(Continued from page 428.)

COMPREHENSIVELY bringing all sorts and conditions of water formation under one head for adornment by planting, the subject, for this purpose, roughly resolves itself into two sections—viz, marginal, and, if we may so term it, body planting. Apart from any purpose of the planter to cultivate certain plants successfully without consideration of ulterior effect, so far as the water is concerned, the fundamental rule upon which to base ideas is to regard water as the *pièce de résistance*, and its planting as a garniture, hence the cautious rather than the lavish hand is essential, whilst discretion as to suitable plants is equally important. Circumstances, however, considerably alter cases, and with comparatively deep water the danger of overcrowding may never present itself so far as the body planting is immediately concerned. He who has seen that most perfect picture of its kind, where here and there *Nymphæa alba*, the white Water Lily, floats to adorn but not to hide the bosom of some fair lake; and who has, per contra, seen that yellow buttoned vagabond, *Nuphar lutea*, absorbing the whole surface, will observe how one enhances and the other obscures the lineaments of beauty. So, too, in a degree with marginal planting, which may briefly claim our attention ere proceeding further.

Here a passing glance must be given to those grand opportunities presented for the introduction of our noble foliage or gorgeous flowering plants on the scene, some of which are peculiarly adapted to the position. One needs but to mention a massive group of *Gunnera manicata* or a bold planting of *Tritoma Uvaria grandiflora*—the first on a promontory, the latter on the flat face of an island or other coign of vantage, to illustrate our text, for there is a host of plants suggesting their suitability to the purpose, according to local conditions of climate, shelter, or space. Coming to those things which, like the boys, love to dabble at the edge without getting out of depth, our theme has fascinations which tempt me to digress, and detail a number of varieties for which, indeed, there is no present need, and very possibly it may be that in certain instances their employment should be severely limited. Here we want no impenetrable barrier—just a clump or two of golden or red Willows, or the same of Dogwood, to brighten up a winter scene, and form a note in the harmony without unduly obtruding, and these, of course, according to scale.

Our young designers will, doubtless, grasp the meaning of much that can be merely hinted at, and from that avoid all pettiness of detail in this as well as in other phases of picturesque gardening. Common things will not be despised as means to an end, although their aggressive character may necessitate their limited use, with provision to keep them within reasonable bounds. Our common Water Flag, *Iris pseud-acorus*, is to my mind so inseparably associated with water scenery, that it is practically indispensable; but there are, I know, hundreds of pools and ponds encircled by an unbroken broad band of this plant during the season of growth, which wholly detracts from the general effect. Isolated clumps nourished into those proportions they are able to assume—viz., some 7 feet high—are very beautiful, and tolerably easy to keep within bounds by a little excavating around them, for this plant loves not the deep water. One other plant only need now be mentioned for marginal planting on the larger scale (on the smaller scale it may take a more prominent place)—this is the common *Calla*, the so-called Lily of the Nile. It is seldom seen thus used, hence the reason for including it here; but it is so satisfactory that it should be free to enter every piece of ornamental water in the kingdom. Respecting its hardiness (sometimes questioned), I have seen it planted in a fountain 2 feet deep, and stand the ordeal of being frozen into a solid block of ice without injury.

Apropos of the main planting in deep water, the highest type of beauty that we can imagine in natural water scenery was that witnessed by Sir Richard Schomburgk, who with his Indian guides paddling down the warm waters of the Berbice entered an open lake to find themselves among groups of that glorious natural triumph, the *Victoria Regia*. From this picture with its high tropical tone we descend but slightly, if at all, in the scale of beauty to bring in our beautiful native Water Lily, *N. alba*, already alluded to. It is *par excellence* the plant for our purpose, and when in the days to come M. Marlia's beautiful hybrids occupy the same position nothing more can be desired in this direction. With water exceeding 5 or 6 feet in depth stations can be made for the purpose of planting, and such things as old crates or hampers weighted with stones and packed with turves about the rhizomes of

FIG. 93—STYLOPHORUM DIPHYLLUM.

the Lilies is an admirable method of introducing them to their permanent home.

Hardy aquatics are, in a measure, limited to a few suitable plants, but for obvious reasons that is not a matter for regret. Amongst bog plants we have a greater variety, many of which are beautiful, and all interesting from the particular features pertaining to their culture. Little difficulty will be found necessary to give certain classes of plants that treatment in which they delight with variations to suit their requirements according to season.

There are few objects more charming than a bold group of *Iris Kämpferi* displaying their soft satiny blossoms of many hues amongst the sword-like foliage. One such glorious planting I saw where the wants of these plants had been catered for by a trickling vein of water admitted to them from the main artery of a stream during the growing season, which was again shut off at the approach of winter, keeping them dry and snug during the season of rest. How different this to the common method of dotting these plants through a hardy border, possibly only to exist on sufferance, and in any case never attaining the effect described above, which was indeed a revelation in picturesque planting. Under nearly similar

conditions the elegant North American *Cypripedium spectabile* flourishes, and a hundred things impatient of orthodox restraint or pampering.

As a connecting link with *terra firma* there are our Filmy Ferns, several of which at least could be happily accommodated in some "cool grot" prepared for their reception by a little labour, as they are by infinite pains taken to grow them under glass. If it were necessary to further plead for picturesque treatment, or to press its claims upon those into whose hands will eventually fall the power to promote it, I would ask them to test my observation a theory advanced by a plant lover—viz., that they—plants—have a kind of family sympathy which induces them to flourish best amongst their own immediate kith and kin. However that may be, grouping is the rule, dotting the exception, in this free gardening.

In concluding this subject the question may arise "How much or how little shall I, as a head gardener, be practically tested in the time to come with this class of work, and consequently what attention need be paid to the subject now?" "There are good all-round gardeners who in their successful orbit have steered clear of all such things." That is so; but we are looking to the future, and expecting the call to move in a much wider circle. Our young men, now, probably can do but little more than catch the spirit of such things—form clear conceptions of those lines of beauty more delicately traced in the kingdom of picturesque gardening than elsewhere probably. It is a great subject—a grand subject, worthy and able to comprehend all the recreation required in a quiet life, and in turning to more prosaic things any ultra-enthusiasm kindled by it will not be quenched, merely tempered by the thought that

"What by duty's voice is bidden,
There where duty's star may guide;
Thither follow, that accomplish,
Whatsoever else betide."

—AN OLD BOY.

(To be continued.)

THE BROCCOLI CROP.

THIS crop, as was generally assumed at the end of last summer, has not realised such a profitable return as might be hoped, and as a result of the drought of last summer, and the drenching nature of the winter and spring, the heads are small, and in many cases very scarce. From a commercial point of view this scarcity has advantages as well as disadvantages, for while in a season of plenty there is so much waste, and the intrinsic value so little, there is quite an opposite aspect when the grower and consumer is brought into keener contact, and the value of the goods is greater proportionately with the demand and supply. There is undoubtedly a keener appreciation of any crop, whether it be garden or field, when it is brought within the limits of the demand.

Broccoli this season has been somewhat erratic, some early kinds coming into use later than usual, while later varieties turned in more quickly than usual. Late Queen, or what was supplied to me for that excellent May Broccoli, was all used up in April, which for me was very convenient. Some other winter sorts had turned in, and would have left a breach but for the hasty maturity of the Late Queen. Model has been very good, and is invariably a most reliable hardy Broccoli; so is the old Leamington. Sutton's newer Mayflower has been equally good, and is a very distinct Broccoli with beautiful white heads; but perhaps the most useful of all is Bouquet, another of Messrs. Sutton's introductions. I have grown this now several years, and always with satisfactory results. Unlike other, or, rather, ordinary Broccolis, this gives several smaller heads from one stem, a characteristic implied by the name it bears. It has a good constitution, and is very hardy, and may legitimately be claimed as good for the palace as well as the cottage garden, because of its freedom and the medium size of the heads. It has one fault, however, and that may be found in the colour of the head, which is not so white as demanded in some establishments, that is under natural conditions of growth. If the flower heads are kept carefully protected from the light and sun a clearer colour would naturally result.

In this neighbourhood there has been a general complaint laid against slugs and the Turnip flea in raising, or attempting to raise, plants from seed for the next winter's supply. Repeated dustings of soot and lime, and for the hindrance of slugs a light dressing of powdered salt, has all apparently been of little avail, for the work of destruction has been in progress for some time, and still continues. April sowings fared worse than others made during the present month, presumably for the reason that May, so far, has been a dry month, when slugs cannot carry on their depredations so easily. Earthworms, too, have been so numerous and busy for the same reason, and assisted the slugs very materially by making convenient hiding places for them during the day. They also

pull many seedlings into the ground, and particularly small ones freshly planted.

There is no doubt but that it is a fatal mistake to plant Broccoli on rich and freshly dug ground. Under such treatment they would make a vigorous growth, very pleasant to look upon in the autumn, but presenting a very different aspect by the end of March in the course of ordinary winters. In such as that of 1894-95 it was common to see the hardiest very severely thinned even when planted in poor and firm soil, and as one cannot foresee what the winter prospects may be, it is a better policy to utilise poor rather than strong ground. This applies to the late winter and spring crops; quite a different course can be, and usually is, taken in the matter of autumn and early winter sorts, as these are ready for use and often cleared away before sharp weather sets in, and where accommodation exists a fairly good breadth can be laid in to continue a supply when outdoor growth is held in check by frost more or less severe.

In small gardens where there is a large demand, and late Broccoli must needs follow another early crop, it is a mistake to sow seeds early—say in March, when they have to remain crowded in the seed bed until June, or even July. The end of April and the first fortnight of May is a better time for sowing the late Broccoli, and also that favourite kind Snow's Winter White. Sown at this date they have not to wait long after they have reached a suitable size for planting. There is no better site than an old Strawberry bed, simply cleared and the plants put out by means of an iron bar. As a rule their growth under such treatment is strong, though short-jointed and sturdy, and is better conditioned for the trying ordeal of a severe or even a moderate winter. Some growers take great pains in preparing their plants, first transplanting them temporarily; but by late sowing the necessity for this course is reduced, and quite as good, if not better, returns are obtained by planting direct from the seed bed. The seed should be thinly sown to allow of the plants gaining size and strength without crowding.—W. S., Wilts.

MY NORTHERN GARDEN IN MAY.

OUR second Alfred has written a prose poem on the garden that he loves. Mine is not so extensive, and not in the sunnier South. We have late seasons and revel in our spring flowers when more fortunate friends are enjoying the beauties of early summer bloom.

A long grey old house, with red tiles, facing west, looking up a garden which has a rise of at least 3 feet; the rise is graduated by two small grass terraces, and all the garden is seen to good advantage from the windows. The boundaries on the north are fine old Beeches, just now in their fairest, tenderest dress of green. As summer advances the shade deepens, and with autumn come the brilliant hues of flame-coloured gold. One tree is always a few days in advance of its fellows, and in the autumn this is particularly noticeable, as it assumes its bright dress nearly a week before its brethren.

South and west you find an Ivied wall and trim Yew hedge, still the pride and glory of one old labourer who had a hand in the planting. An Elm tree shuts in the south-west corner. Every scrap of the old house wall is covered with some green thing. A "Gloire" and purple Clematis come first, then Pyrus and Jasmine. Then a Reine Marie Henriette, then Lamarque, and Scarlet Tropaeolum are in close quarters. More Jasmine, and a plant or two of *Echemocarpus*. Then a delicate but highly treasured white Japanese Rose, almost overpowered by her more robust brother, with his lovely rosy pink blooms. Poor old John Hopper comes next; then to prevent the clashing of colours between him and Crimson Rambler is Marie Van Houtte, ever constant with her sweet buds, both the earliest and latest in the garden. A bit of *Ampelopsis* is growing round one nursery window, while the other is encircled by the Ayrshire Ruga huddled on a stand, and of tremendous length. It is the happy home of a pair of sparrows, and the little maiden, the princess of the nursery, looks upon them and the Roses as her very own.

Too near the windows at the north end, but too beautiful to move, is a crimson Chestnut, and we would rather be a little short of light than do away with its fan-like leaves and rosy pyramids of bloom.

On a grass border under the windows had been gay beds of *Polyanthuses*, old-fashioned Tulips, and some rare new Forget-me-nots, the bluest of the blue, and compactest of the compact. Fuchsias and Begonias now take the place of these dead beauties; but we always part with our first spring flowers regretfully. In every corner, nestling among Ferns, are clumps of Wordsworth Poppies. They have, and are still encroaching, and every year we say, Go you must; but every year they look so bright, and weather, wind, and frost, that their day is prolonged. *Corydalis* (the yellow variety) has got a footing, and keeps it too.

Three steps will land you on the lawn. The two *Trifolium* beds in spring are one mass of Harbinger, surrounded by four crescents of Forget-me-not. A long narrow bed passing north and south is given over to Jonquils. Here they flourish literally by thousands, and the double ones too find a home on the south side of the Beeches. Earlier we rejoiced in Daffodils of various sizes and names, from the fairy-like *N. nanus* to the glorious Emperor and the good old-fashioned double.

Just now the Columbines are in their glory, not the Aquilegias of the

nurseryman, but the old-fashioned woodland flowers, so varied in tint, so graceful in form, so prettily set above their delicate greenery. A great clump of Lords and Ladies hide in a snug corner. Did you ever notice how beautiful they are? flower and leaf alike, quite fit for any garden. A bush of white Lilac reveals itself by scent, such as no shop in Bond Street can rival; and across the lawn, just out of the boundary of the Rose domain, is a Sweet Briar bush guarding the Lily patch. The gentle rain to-day will have done its work, and to-morrow we shall have a few sprays of the white bells for our writing table. The pink Pæonies are just bursting, and the Syringa (Philadelphus) will not be far behind, in time this year to deck a bride's table. If it were a hothouse flower what a high value would be set on it; being humble enough for the poor man's garden it is counted of little worth.

The Yew hedge, undisturbed this year by the active schoolboy, is full of nests, and the whole garden is one concert room. The Roses have borne the winter well, and are breaking in every direction. The Rose-trellised walk is one thick tangle of bronze and green and wee buds that give promise of a glorious hereafter. This is only the homely garden of a farmhouse, easily managed with little expense, but a source of endless pleasure to its owner.—THE MISSUS.

SUMMER BEDDING.

(Continued from page 432.)

I REFERRED on page 432 to the arrangement of beds. I will now pass on to the borders, which to my mind are much the prettier if not made too formal. A wide border by the side of a long straight walk may be made to look effective in the following way. A back row of Conifers of various sorts, about 7 or 8 feet high; between each plant a clump of Hollyhocks and tall Michaelmas Daisies, such sorts as *Asters novæ-angliæ rosea*, *n.-a. rubra*, *diffusus pendula*, *Harper Crew*, *patulus*, *paniculatus*, *Lady Trevelyan*, *floribundus*, *Robert Parker* and *polyphyllus*. By planting Hollyhocks and Daisies in one clump you get a continuous block of flowers, for as soon as the former are over the latter begin and keep on till the end of the summer. In the next row, 3 feet from the back, plant another line of Conifers about 3½ feet high, just opposite the Hollyhocks, such as *Retinosporas plumosa*, *plumosa aurea*, *plumosa argentea*, and *plumosa vera*; these can be kept neat and to any desired height with knife and pruning scissors. Clumps of Cannas that grow from 4 to 5 feet high may be placed to come opposite the back Conifers. In the next row, 3 feet distant, put dwarf plants of *Acer Negundo variegata* just opposite the Cannas. These can be pruned back every year to keep them dwarf, and between each of these plant a purple Japanese Maple, or purple-leaved Castor Oil (*Ricinus Gibsoni*). About 18 inches from the Acers have a row of *Sedum spectabilis purpureum*, a foot apart in the row, and at every 4½ feet along this row plant alternately *Hydrangea paniculata* and *Lilium lancifolium roseum*; let the Lilioms come opposite the Acers, and the Hydrangeas opposite the Castor Oils. About 18 inches from the *Sedum* a row of tuberous rooted Begonias may be planted, and 1 foot from this tuberous Begonias again. Now, between these two rows of Begonias, at every 9 feet, place a Fuchsia which has previously been grown up to about 2½ or 3 feet high, with not too many branches up the stem, or it will hide the Begonias too much when looking up or down the border. In the next row, 9 inches from the Begonias, plant Golden Feather, and 6 inches from this a double row of *Ajuga reptans*, to fill up to the Box, tile, or whatever permanent edging is used. This border will be about 12 feet from the Box edging to the centre stems of the back row of Conifers; altogether it would require to be about 14 feet wide. We have such a border at Sandhurst Lodge, on either side of a straight gravel walk leading to the inside kitchen garden, which is bedded every summer, something after the style I have described, and is always greatly admired by visitors. Sometimes the front is done in beds, sometimes in lines, but never two seasons alike.

Mixed borders again are always effective and interesting if they are properly planted. If you can get a long border about 9 feet wide by far the prettiest way is to plant in groups, each kind to occupy a space, say about 5 feet long by 3 wide or so; if a little larger all the better. These borders may be filled principally with hardy plants, but spaces should be left for tender plants and annuals, which must be arranged so that the border shows bloom from one end to the other the whole summer. When planting mixed borders care should be taken not to have two groups of plants together that bloom early and are over for the rest of the season; but against an early flowering group plant one that blooms later, then you will have a continuous border of flowers for a very long season. I use very few stakes in my borders. If a plant can any way be grown without a stake I never use one, as the border looks so very much prettier without them; and I never cut my herbaceous plants down till the end of the season, only keep taking off the dead flower heads down to the first green leaves, as the old stems not only help to strengthen the roots, but keep the neighbouring plants up in rough windy weather.

And now for a word about pot Fuchsias and other plants which are very effective in groups, plunged to the rim of the pot in the grass. This is done at Sandhurst Lodge, and these groups are always greatly admired by visitors. These, to my fancy, should be arranged where a good background of green foliage can be had to set them off to the best advantage. They may be arranged in the following way:—Say a group of all Fuchsias of different colours, and then a large group of mixed plants, such as *Plumbago capensis*, *Plumbago capensis alba*, *Solanum*

jasminoides, *Habrothamnuses elegans*, *coccinea*, and *aurantiaca*, *Swainsonia alba*, *Swainsonia Osborni*, large plants of *Zonal Geraniums*, *Erythrina crista-galli*, *Brugmansia Knighti*, *Begonia Ingrami* and *fuchsoides*, *Cobæa scandens*, *Ivy-leaved Geraniums*, and *Tropæolum Fire King*. The three latter must be trained round stakes, and then allowed to branch out and hang about in a careless manner, with a tall Bamboo or two arranged here and there. A very interesting and effective group may be made somewhere near the mansion with the different sorts of scented-leaved "Geraniums." The flowers of some of these are very pretty, and they are as a rule continuous bloomers. Such sorts may be used as *Rollinson's Unique*, *Prince of Orange*, *Fair Ellen*, *Lady Mary*, *Shottesham Pat*, *Lady Scarborough*, and *quercifolium*.

Perhaps before I go further I might give a list of Fuchsias, which with me have proved to do well outdoors, both in pots and planted out. The single varieties are undoubtedly the freest and most continuous bloomers. Amongst these are *Charming*, *Mr. King*, *Blushing Bride*, *Cannell's Gem*, *Countess of Aberdeen*, *Display*, *Victor Hugo*, *Erecta*, *Novelty*, *Daniel Lambert*, *Dr. Lancaster*, *Rose of Castile*, *Alba coccinea*, *Anrora Superba*, *Mrs. Rundle*, *General Roberts*, and *Rose of Castile Improved*. The best doubles that I know are *Madame Jules Chrétien*, *Edmond About*, *Berliner Kind*, *Dr. Matthews*, *Elizabeth Marshall*, and *Frau Emma Topfer*. These are all good and free flowering sorts, the last-named is a fine bloom but not so free as the foregoing.

All these pot plants should be arranged with an eye to colour, and have sufficient width of green turf between them to enable you to get about easily for mowing, tying, and watering the plants, the rim of the pot being plunged down level to the turf, and a few clinkers or cinders put at the bottom of each hole to insure free drainage. These plants require abundance of water on hot sunny days, and they must also have careful feeding; and here lies the secret of success, for nothing to my mind looks more miserable than a shabby plant placed out on a lawn in a flower pot. My plan of feeding is a very simple one, and is as follows: Two paraffin casks are procured. In one is put a bag containing about two gallons of soot, and in the other cask about a gallon and a half of guano, both are then filled with water, and allowed to stand a day. To three gallons of clear water a half-pint of one or other of these mixtures is used for watering the plants every morning, other supplies of clear water being given during the day. The soot bag will last about a month, but the guano tub will want a few handfuls throwing in every few mornings; before taking the guano water out stir the contents of the tub, and then allow it to settle again. Besides these two stimulants I use very weak cow manure water, which runs into a tank from the cow yard, but my plan is to use all stimulants weak and often, and to keep changing from one to the other.—(Read by Mr. W. TOWNSEND at a meeting of the Reading Gardeners' Association.)

(To be concluded.)

RED SPIDER AND GOOSEBERRIES.

THIS is one of the most troublesome of the gardener's enemies, and in order to combat it successfully action requires to be taken in the early stages of the trees' growth. Our Gooseberries are all cultivated on trellis (cordon system), the length of each trellis being 150 feet, and the height 5 feet. We had a rather severe attack of the red spider, owing, no doubt, to the prevalence of dry weather accompanied almost incessantly with N.E. winds (this being conducive to the well being of the enemy), and which shows signs of spreading to an alarming degree. I applied spidicide with the syringe about once a week, with heavy syringings of clean water two days after each application. I can safely say that it has proved to be efficacious. The trees are now clean and healthy, and growing most luxuriantly, being laden with large quantities of fruit, and the foliage of a beautiful dark green. I have no doubt there are other preparations which would exterminate these insects effectually. I have no interest in recommending spidicide other than that it has done that which the makers claim for it. I have no doubt Mr. Hiam's plan is a good one (page 418), but it would seem to need a microscope and white paper to perceive the insects. Those on our trees were plainly visible with the naked eye.—H. T. MARTIN, *Stoneleigh Abbey Gardens*.

RESPONDING to your invite for information of remedies for the extirpation of that exceedingly troublesome insect *Acarus* (*Tetranychus*) telarius allow me to remark that one of the most efficacious preventives and cures I am cognisant of is a copious syringing with a mixture of flowers of sulphur and petroleum, well incorporated with water at the rate of two wineglassfuls of the oil to a gallon of water, or instead of the sulphur a little softsoap added to the oil, with, say, a pint of boiling water, thoroughly churned together before mixing with the water for use. The softsoap has the effect of causing the oil to intermix more intimately with the water.

It will be readily conceded that it is somewhat difficult to apply the liquid underneath the foliage, which forms the chief resort of the spider, especially during wet weather or when the upper surface of the leaves are covered with dew.

As it is somewhat difficult to apply the liquid on the under surface of the leaves, especially where the branches are trained within a few inches of the ground—a mode generally adopted by exhibition growers—it is necessary to employ something more suitable than the ordinary rosed syringe. I have used an angle-jointed rose syringe for the purpose

also, as infinitely preferable, a hand pump with a sufficient length of rubber hose attached, with which appliance a large number of bushes can be readily dressed in a comparatively short time, especially if an assistant works the pump, and thus leaves the other operator to use the hose with a rose or nozzle attached more freely with one hand, and the other holding up the branches of the trees. The advantages of this are obvious.

I may add that the best period of the day is when the insects are roaming over the dry upper surface of the foliage, as well as beneath. I recommend the insecticide in question as one of the least expensive, as well as most efficacious; otherwise there are several other equally effective remedies, and one of the cheapest, though most difficult to apply on account of its adhesiveness to the implement employed, is ammoniacal liquor or gas water mixed with clear water, but which difficulty may be ameliorated by the addition of a little soft soap, as recommended for the petroleum oil.—W. G.

THE FLOWER GARDENS OF VICTORIA (AUSTRALIA).

(Concluded from page 414.)

TOWARDS the latter end of summer and early autumn the Lilliums are in their best form, and are easily grown. The beautiful Nile Lily grows freely everywhere, and to immense size. Fuchsias are so common as to be rather despised, and embrace many kinds, the little "Baby Fuchsia," as it is called there, growing into quite a tree. Poppies are in endless variety of size, shape, and colour, and these also bloom better the hotter the day, the French varieties, and one we call the Maltese, from the cross seen in the petals, being special favourites. Cacti, crimson, pink, yellow, and white, grow splendidly and to great perfection in the hot weather. Cornflowers of four or five different colours are to be seen in nearly every garden. Eschscholtzias, Dianthus, Pinks, Picotees, Salpiglossis, Godetias, Gardenias, and Heliotropes are splendid bloomers in the summer, and always look showy. Everlasting Flowers grow to great perfection, some of the indigenous wild ones found in the country doing well with a little culture. Hollyhocks grow to a great size, and the flowers are very large; one fine one of a delicate lemon yellow colour looks specially attractive.

From earliest summer the Roses are in bloom, and before Christmas the Rose shows are held, and draw great crowds of exhibitors and enthusiasts. This queen of flowers grows to great perfection, and in a manner that would astonish English growers. I have heard this from competent judges. I cannot remember the names of varieties in such a large class, so can only generalise; but the old favourites, like *Maréchal Niel*, *Cloth of Gold*, *Souvenir de la Malmaison*, *Niphetos*, *Safrano*, *Madame Lambard*, and *Gloire de Dijon* are to be seen in scores of gardens climbing up verandahs, side fences, walls, or on lattices. *La France* luxuriates, and along with *Safrano* is a real marvel to bloom—indeed, one can almost always get *Safrano* flowers. The *Banksias*, white and yellow, are much sought after, making excellent verandah shades and fernery coverings. I have seen the front of a one-story house covered with the blooms of a yellow *Banksia*. The following note is from a letter from Australia I received about fourteen days ago:—"In our garden everything is looking so fresh and green, and quite a lovely mass of blooms of Roses, Asters, Sunflowers (the large and miniature), *Gladioli*, and the lovely light blue *Plumbago*, also a splendid crop of *Gaillardias*." I will ask you to note that this is in the middle of our hottest month (February), and is Nature's response to a recent rain, which has just refreshed the land. Among the later Roses introduced to Melbourne may be mentioned the charming *petite Rose*, *Madame Cecile Brunner*. It is especially in favour for gentlemen's buttonholes, and grows to perfection.

Dahlias of all varieties grow magnificently everywhere, and are universal. The pretty *Cactus* section seems to have become a general favourite, though only comparatively recently introduced. *Sunflowers* raise their tall heads, and the smaller *Miniature* is a prolific bloomer, and makes a garden look gay in the hottest days when other things are hanging out distress signals from the heat. With the autumn gardens are just beginning to lose their beauty, and many of the plants are in seed, or taken out. *Hydrangeas* are growing in most gardens, and bearing immense beads of blossom, blue, lilac, and white and pink; but now we are again saved by a wealth of *Chrysanthemums*. These are grown to great perfection, and are immense favourites; and of hundreds of varieties blooming well on into winter *Pompons* incurved, outcurved *Japanese* are to be found. Everyone grows them, and one gets rather a sickening of the word, for everyone wears them, everyone almost talks *Chrysanthemums*, and shows are the order of the day. Some grown in *Wentworth, N.S.W.*, by a Mr. Higgins always create a sensation. Arriving too late for the big shows in Melbourne these blooms are sent over 300 miles, and exhibited in the florists, and seem to dwarf the first prize ones in the shows. I would like to see some sent to London if it could be done, because they would then speak for themselves. *Chrysanthemum* growing is a mania in Australia.

During the winter months or season, which is generally well on us by the middle of May, gardens are seen at their worst, the bare deciduous trees helping in a large measure in this respect. Cold winds, rain, hail, frosts, and occasionally, in some districts, snow, all make the ground sopping and cold. *Camellias* are now in full flower, and the trees grow

into immense size, even up to 10 feet high. Single and double, and of all colours, the blooms grow to great size and perfection. *Pyrus japonica* does remarkably well late in the winter, while *Bouvardias* are now making a splendid sight; but, as remarked, gardens are looking bare just now.

The end of July sees the days lengthening and the sun's rays warming up, the cold sodden grounds and plants begin to put on some growth, and by the time August is well in Nature seems trying her utmost to make up for past misdeemeanour, and transforming everything. The fruit trees are one mass of blossom, and the bees are busy in swarms over the heavily scented blossoms. Later the green leaves and rapid growth of all spring plants can be detected. *Violets* are in great variety, and almost every small garden has its border or plat of them. *Daffodils*, *Primulas*, *Cowslips*, *Oxlips*, *Primroses*, *Auriculas*, *Ixias*, *Tulips*, and *Crocuses*, all are giving signs of great promise, and many of them flower early.

With September spring is in full tide, and the *Narcissus* family reigns everywhere: *Daffodil* shows are the order of the day, and competition is the means of bringing out beautiful displays of bulbs in full and excellent flower. *Hyacinths* are good, but except in the mountainous or higher grounds seem to lack something, and are not so fine as in England. *Camellias* (early), *Bouvardias* (crimson and white), *Salvias* of three or four sorts are all helping to adorn the gardens. *Wallflowers* bloom luxuriantly, and these flowers and *Mignonette* can be smelt on every humid breath that blows. *Wallflowers* will grow anywhere with us, and well, provided the place be not absolutely cold and wet. *Daisies*, *Marguerites*, early *Calliopsis*, *Cinerarias*, *Myosotis* (notably a large variety whose name I do not know) now remain flowering right on into midsummer. *Asters*, *Lupins*, *Larkspurs*, and *Anemones*, one especially fine scarlet variety doing splendidly, and attracting much notice. The *Cosmos* are all coming into bloom. Melbourne, and indeed Australia, wherever a garden can be obtained, has lately had a craze for the lovely *Cosmos*, and I have seen them often 5 feet high and covered with their beautiful delicate blooms of white, purple, and pink. They require plentiful watering to grow to the above height. *Gaillardias* are extremely hardy, and one can chop them back, and yet with a little watering they bloom persistently throughout the long summer, and sometimes the flowers reach really giant proportions. *Nemophilas*, *Godetias*, *Candy-tuft*, *Sweet William*, and *Lobelia* are now either in full flower or nearly so, and bloom for a long time.

About the shrubs and trees I cannot say much, but some are such well-known ones that I can remember them. *Lanrustinus* is very common, and grows and blossoms splendidly. *Rhododendrons* and *Pittosporums*, the latter bearing blooms of two shades of colour, a cream and a purple, grow into huge trees and hedges, and in springtime the night air is really heavy with their perfume. They are the commonest shrubs found in our gardens. *Abutilons* behave splendidly in our climate, especially in the cooler districts. *Solanums* grow to immense size, and their brilliant fruit makes a lovely contrast to their bright green leaves. The *Indian Shot* or *Canna* is a strong and good grower. *Hakeas*, *Grevilleas*, *Flowering Gums*, one specially fine being *Eucalyptus ficifolia*, bearing crowds of blooms. *Magnolias* bloom in great profusion, while no garden is deemed complete without its *Daphne* plant. *Habrothamnus* and *Salvia* grow into large trees, and are splendid flower bearers. The *Bottle-brush* or *Callistemon* has beautiful singular flowers of scarlet, crimson, and purple. The *Sterculia acerifolia* bears rich masses of vermilion blossoms, like bunches of coral. *Melaleucas* or *Tea Tree*, *Lophostemons*, *Currijongs* are all showy shrubs, and bloom splendidly.

In a country necessitating shade verandahs are to be found on every house, and naturally everyone grows some sort of a creeper on the posts or on wire stretched between them, or on lattices or porches, getting thereby ornament and usefulness in the shape of shade and privacy. Thus one finds *Bignonias*, *Convolvuli*, *Jasmine*, *Honeysuckle*, *Clematis*, *Periwinkle*, *Wistaria*, *Tecomas*, *Grevilleas*, *Banksia*, and all sorts of climbing *Roses*. *Passion Flowers* of the ordinary crimson and edible varieties, the latter a prolific fruit bearer if planted in the right aspect, are common. *Virginia Creeper* of two sorts is a favourite on every brick-walled or cement-covered house.

I must now mention one or two plants which are indigenous to Australia. One is *Sturt's* lovely *Desert Pea*, with its brilliant crimson and black flowers. In a hot dry soil this plant grows to perfection, and one can well imagine the surprise and delight felt by the explorer whose name it bears on his first coming on to a vast plain covered for acres with this glory. Another plant is the *Boronia*. It has the most subtle perfume, and is a native of West Australia, where there are plains covered with it. When in bloom the perfume-laden breezes blowing from over these plains are said to be simply intoxicating.

Now I must stop. My object has been to try and give you the idea that we can grow in and around Melbourne and throughout the colonies of Victoria, and in much of N.S.W., any of the flowers to be found in England, as well as numerous others from different parts of the world, with of course those which are indigenous to the colonies of Australasia. There are many with whose names I am not familiar, and which would take an abler pen than mine to treat of in decent order.—(Read by DR. ERNEST D'OMBRAIN of Melbourne at a recent meeting of the Horticultural Club.)

ROSE SHOW FIXTURES FOR 1897.

- June 7th (Monday).—Cambridge.
 „ 9th (Wednesday).—Chelmsford.
 „ 15th (Tuesday).—Ryde.
 „ 16th (Wednesday).—York.†
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 23rd (Wednesday).—Richmond, Surrey.
 „ 24th (Thursday).—Colchester.
 „ 25th (Friday).—Maidstone.
 „ 26th (Saturday).—Windsor and Dorking.
 „ 29th (Tuesday).—Canterbury, Hereford, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon, Ealing, Farnham, and Reading.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 6th (Tuesday).—Diss.
 „ 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
 „ 8th (Thursday).—Bath, Farningham, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.
 „ 10th (Saturday).—Manchester.
 „ 13th (Tuesday).—Wolverhampton.†
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 17th (Saturday).—New Brighton.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.
 „ 28th (Wednesday).—Chester.*
 „ 31st (Saturday).—Liverpool.*

* Shows lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

FARNINGHAM ROSE SOCIETY.

THE schedule of this Show, which is to be held on July 8th, has been sent to us. It is divided into eight sections, three of them based on the number of Roses (plants) grown. Three classes—namely, thirty-six Roses, eighteen Teas or Noisettes, and nine triplets of the same—are open to nurserymen and all comers who are subscribers. A ladies' section is provided for floral decorations, and the classes, we believe, are usually well filled. Classes are also provided for amateur gardeners and cottagers, not confined to Roses, the object being the improvement of horticulture and floriculture in the district. General Edwardes, C.B., is the Honorary Secretary.

COMMENTS AND IMPRESSIONS.—MANURES.

THE kindly editorial postscript appended to my last notes was encouraging though somewhat too flattering, but it has induced me to attempt another letter in the endeavour to keep the promise I then made to say something about so-called artificial manures and their effects on Roses. Some years ago my attention was called to this subject by a conversation with two rosarian friends, one of whom had been employing guano, and the other bonemeal for their Rose beds. Each was convinced that special advantage had resulted from the use of the particular substance he had tried, and it appeared so clear that conspicuous effects had been produced in comparison with ordinary stable manure that I resolved to try both the manures myself.

An early opportunity was afforded for doing so, as I had a quantity of well-rooted cuttings of many varieties, both Hybrid Perpetuals and Teas, and I thought that by taking a dozen each of about six varieties differing in habit and colour, I should have enough for testing. The varieties selected were La France, Charles Lefebvre, Général Jacqueminot, John Hopper, Gloire de Dijon, and Niphetos, which offered sufficient range in their chief characters for a first experiment. Three beds were formed 12 feet long and 8 feet wide, the soil being a moderately heavy deep loam resting on gravel. These were well dug, and received an ordinary dressing of rather old decomposed stable manure, which was incorporated with the soil as the work proceeded. In each of the beds twenty-four young plants (one year old cuttings) were planted at 2 feet apart—i.e., four of each of the varieties selected, so that they were as uniform as possible. The planting was done in open weather at the end of November, as a matter of personal convenience, and not for any special reason.

To one of the beds a fairly heavy dressing of stable manure, from which all the long portion had been removed, and which had been in a heap for a month, was given, on the surface immediately after planting, with a lighter application in the following spring. Altogether the

amount would be about equal to 20 tons per acre. No. 2 bed received a double dressing of a good bonemeal containing a large per-centage of soluble phosphates, the application being made at the rate of 1 oz. per square yard after planting, and again in March. The third bed had a dressing of an excellent nitrogenous guano (Ichaboe), applied at the rate of 1 oz. per square yard in February. The amount and times of the respective applications were arbitrary—that is, they were not founded upon any definite rule or experiment, except as regards the probability of their becoming available by the plants as growth commenced.

Practically, as regards the bonemeal and the guano, the comparison was being made between the effects of nitrogen as ammonia and phosphoric acid as phosphates, the stable manure being regarded as a mixture possibly containing all the substances required by the Rose, but in uncertain proportions, and tending further by its peculiar constitution to materially affect the soil and roots apart from its chemical constitution altogether. This was really the point I had a desire to investigate, for though stable or farmyard manure was a satisfactory application on the soil I was then dealing with, yet in previous experience on heavier and more adhesive soil it had been observed that the dressings of this manure rendered the surface wet, cold, and more difficult to aerate, with corresponding evil effects upon all Roses, but especially upon those of weak habit. Coolness and moisture are undoubtedly advantageous to the roots of the Rose, especially in a hot dry summer, but in an unfavourable season the effects of a heavy dressing of wet manure are the reverse of beneficial on many soils. The success of my friends with the substances being tried in comparison with the ordinary manure suggested the possibility of determining what constituent was essential, and whether foliage or flowers were most affected by the particular substance.—A MIDLAND ROSARIAN.

INSECT INVASION.

THANKS many to "W." Why he should be so concerned about my alphabeticals I cannot imagine; there is no novelty about them, and they have appeared occasionally, as time and temper allowed, in our journal for the past thirty years and more. There is some charm about a *nom de plume*. All of us would be sorry to miss "D. Deal," or "W. R. Raillem." By-the-by, I have only this year discovered the owner by his few lines on early Rose budding—the lady's brother being a great friend of my own, and had already told me the circumstances, and now I still would sooner see "W. R. Raillem" than his right name, and for the few months or years that I may still be privileged to use the pen the "fanciful" alphabeticals will generally be my signature.

"W." does not say in so many words that ordinary tobacco fumigation persisted in will kill the eggs of aphides. I said in my few lines that I was coming to the opinion that the XL vapouriser had some power over the eggs. I do not think that the general opinion is that ordinary tobacco fumigation can destroy the eggs, for if so, why in a badly infested house were we advised to smoke, and repeat the same in two or three days? Certainly since the aphides on the Chrysanthemums were destroyed by the XL in the autumn I do not think I have seen a green or any coloured aphid in my house. Cicerarias, Pelargoniums, and Roses are all likely to show them, but they are perfectly clean.

What a pity "W." had not been a little more explicit. What does "light periodical fumigation" amount to? Does it mean a gentle dose, such as would not be sufficient to destroy aphides, supposing they were in force? Personally I have little faith in light fumigation. I know friends who smoke their cigars in the greenhouse, I do myself, but not with their notions, that the smoke is good for cleaning the plants. Then seeing I confessed myself an ignoramus, I should have been glad to know what time was allowed between the "periodical" fumigations, and whether the size of the house altered the time. Like the Editor, I have had insect pests sent to me which soon found their way to the fire—that most useful destroyer.

"Some persons appear to be in their glory among insects, which they seem to tend so lovingly," so writes "W." And no wonder. Truly we live under the curse of labour for sin, and a gardener's life is one of continual labour, I grant, but even in the insect world there are our helpers in labour, and it is no wonder if some amongst us, who know their value, who "glory" in them, should "tend them so lovingly." Here, as my experience goes, we may teach gardeners a wrinkle or two if they will only condescend to learn all insects are not pests.

For "W.'s" information I may tell him I am an old learner, getting on in the seventies, and prefer to be my own gardener. I thus do just as I like, and I have no intention of getting "rid of myself;" also, so long as the Editor thinks it worth while to print me, I intend to stick to my "fanciful alphabetical" cognomen. In growing plants, Peaches, and Grapes "without an insect on them," surely "W." does not mean that his periodical fumigation cures red spider. How does he treat them?—Y. B. A. Z.

[It is gratifying to observe not only the firm clear penmanship, but the alertness of our septuagenarian correspondent. The Journal could not have reached his address, more than 100 miles from London, till some time during last Thursday, while the above communication was in our hands on Friday, and the compositors have rarely better "copy" placed before them. We hope the "time and temper" of our old friend are far from being exhausted.]

WEATHER IN LONDON.—Since sending our last impression to the machines, a considerable amount of refreshing and invigorating rain has fallen. Throughout the Temple Show, as well as on Saturday, showers were heavy and frequent. On Sunday evening, and at four o'clock on Tuesday morning, there were thunderstorms accompanied by drenching rains. Wednesday opened dull but fine.

— **WEATHER IN THE NORTH.**—Throughout the last week of May rain fell plentifully in gentle showers, and a genial atmosphere has generally prevailed, although there has occasionally been a recurrence of the cold easterly winds. In every department vegetation has made a great advance.—B. D., *S. Perthshire*.

— **AWARDS AT THE TEMPLE SHOW.**—In the official list of awards at the Temple Show the names of Messrs. Sutton & Sons, Reading; J. Carter & Co., High Holborn; and C. Beckett, gardener to Sir W. G. Pearce, Hungerford, were omitted. Each of these received silver cups for their contributions to the display.

— **EARLY PEAS.**—A correspondent writes:—"You may be interested to note that Eclipse Peas were picked at Evesham on May 31st. From the same bank Eclipse was first picked on May 31st in 1895, and May 21st, 1896. The Peas were sown in December, with Radishes, and had the advantage of being covered with straw till the Radishes were up. No other special culture was given."

— **NEW POTATOES IN ISLE OF WIGHT.**—Mr. James Mackett of Bembridge sent me a few days ago some new Potatoes (Sutton's Ring-leader) which had been grown in the open air without any protection whatever. The sets, nicely speared, were planted on a S.E. border, well sheltered by a high hedge, on the 21st February, and the first Potatoes dug May 10th, the heaviest tuber weighing 4 ozs.—S. HEATON.

— **GARDENING FOR ALL.**—Mr. James Udale, Chief Instructor in Horticulture under the Worcestershire County Council, has sent us a copy of the second edition of his Handbook on Gardening. It is, as its title implies, comprehensive, and the many subjects are of necessity concisely treated, the greatest amount of space being wisely given to the more important. These are dealt with in a manner that cannot fail to be helpful to those who desire scientific and practical information bearing on the cultivation of the soil and the production of serviceable crops, while popular window and garden plants are not overlooked. Lord Cobham, who has evidently a strong desire to see allotment holders improve their position in life by intelligent industry, writes an excellent commendatory introduction, and truly remarks, "Horticulture is a delight to most right-minded persons, including those who are untrained and unscientific; but it cannot be doubted that the more knowledge there is of the mysteries and phenomena of life and growth, the more grasp of the principles upon which all progress and skilled experiment must be founded, the truer and higher will be the pleasure." The Rev. F. R. Lawson contributes an equally excellent preface, one paragraph of which may be cited, and appropriately headed as follows:—

— **THE DELIGHTS OF GARDENING.**—"It is, on every ground, a matter of deep satisfaction that there is a general increase in gardening knowledge and gardening skill. There is in horticulture a charm which enlarges as its students advance in the understanding and the practice of it. It brings delight to the beginner, and a yet deeper satisfaction to the veteran. There is delight in the first crop from our own sowing, in the first fruit from trees of our own grafting, in the maiden blooms of the Rose which, with anxiety, labour, and some loss of blood, one first budded. But better still, the delight of later years, when the man, a learner still, is also a teacher, when the lessons of mistakes have been acquired, and when some parts of God's varied laws of growth are better understood." Here is a lesson to all; and they are many, who are, unfortunately for themselves, "wise in their own conceit," and we give the Rector's significant words as wide a circulation as we can. Worcestershire is fortunate in having such patrons of gardening on its County Council as Lord Cobham and Mr. Lawson, also such a competent teacher of the ancient, useful, and delightful art as Mr. James Udale.

— **LONDON SPARROWS AND BAND MUSIC.**—Undismayed by the daily Monday to Friday performance of the Press Band in the Embankment Gardens, a pair of sparrows have built a nest in the ornamental ironwork of the band stand, immediately over the conductor's head, and within a few feet of his bâton. Here a young family is being reared, with apparently healthy appetites; for the old birds, taking no notice of the performers, even in the loudest passages, nor of the big crowd of listeners surrounding them, come every few minutes to their untidy nest and feed the youngsters.

— **STRAWBERRIES FOR THE JUBILEE.**—At the Floral Hall, Covent Garden Market, there is evidently no belief in the suggestion that there will be a scarcity of Strawberries for the coming Diamond Jubilee. Mr. J. B. Thomas writes from that address: "The first outdoor English fruit was gathered on May 24th, and sold in Covent Garden on the following day, and the reports from the growers indicate that the prospects are one of abundance such as seldom or never before has been experienced on the banks of the Tamar, and not one has been affected by the frosts. In South Hants in few exceptional places we hear of the sad effects of the cold nights, but the fact remains that empties ordered are double the quantity of last year's requirements, and which have been considerably increased since. In fact, before the frosts the quantity of bloom showing up for fruit would have necessitated the importation of labour from the adjoining towns to such an extent that can only be appreciated by those who know the demand for same during the Kent Hop-picking season. After the second week in June contracts for Strawberries can be made from 20 to 30 tons a day."

— **RHODODENDRON KEWENSE.**—In the Rhododendron dell at Kew several large plants of this beautiful Rhododendron are in full flower. At the present time rare, and found only in choice collections, its beauty and distinctiveness will make it one of the most eagerly sought after of all Rhododendrons in the near future. It is a hybrid between *R. Griffithianum* and *R. Hookeri*. In general appearance it resembles *R. Griffithianum* much more strongly than its other parent, though quite distinct from either. The leaves are from 8 to 10 inches in length, by 2½ to 3 inches in width, deep green in colour, and produced in sufficient quantity to hide all the branches. The flowers are usually produced ten or twelve, sometimes more, together in a loose head. The flowers are large, measuring 3 to 4 inches across when fully expanded. The tube is 1½ to 2 inches in length, quarter of an inch wide at the base, and widens rapidly to 1½ inch just below the free portions of the corolla. In some instances the flowers are found almost pure white, in others they are suffused with rose, in all cases they are strongly scented. The plants at Kew are growing on a bank in a somewhat shaded position at the south end of the dell before mentioned. When planting this variety care should be taken not to give it such a position that the sun will catch it first thing in the morning, as when the growths are young they are more tender than those of the *R. catawbiense* or *R. ponticum* hybrids, and the early sun after a night's frost often injures them. Stocks of *R. ponticum* or, better still, *R. catawbiense*, may be used to work this on.—W. D.

— **HORTICULTURE.**—Probably the clearest definition of the word "horticulture" we have met with, says a contemporary, is contained in the following extract:—"Horticulture is more than a mere trade; it is more than a productive industry. Its successful practice is based upon great laws which have been deduced from the natural and physical sciences. Many of these laws may be arrested, modified, or set in motion at will. The horticulturist, as he learns that the control of these laws is largely in his own hands, becomes an enthusiastic student and investigator, and can scarcely fail to develop a love for rural life—a love that is deep and abiding. Horticulture may justly rank as a science as well as an art. Not to speak of the science of the propagation of plants or the science of tillage, the great fundamental principles of evolution are exemplified in horticulture as nowhere else. Over 6000 species of plants are cultivated by the horticulturist, and these have produced almost an infinite number of distinct forms. In these forms, with their wonderful and intricate variations, we can study the laws of genesis, and master minds are rapidly reducing the wealth of facts found in greenhouse, garden, and orchard to the semblance of an orderly, systematic, and progressive science. The influence of natural and artificial selection, the effect of soil, climate, and moisture upon development, the transmission of acquired characters, the formation of new species, are revealed in horticulture as in an open book. Here facts take the place of conjecture, and demonstration is substituted for theory."

— WELL-GROWN CINERARIAS.—Mr. Thomas Weager, Hill Grove Gardens, Abergavenny, sends us a photograph of Cinerarias. The plants were evidently very fine, and we cannot think they are adequately represented in the impression before us. One plant—a close head of bloom—we are informed measured 8 feet 2½ inches in circumference, in which case it must, judging by relative proportions, be in a very large pot indeed. The size is not mentioned, but it is stated that the plants were raised from seeds (Kelway's) sown during the first week of July last. They represent excellent cultivation.

— THE DEVON AND EXETER GARDENERS' ASSOCIATION.—The summer excursions of this Association have been so invariably enjoyable and profitable to the members that the Committee have arranged for the next one to take place on Wednesday, July 14th, the destination being Plymouth. By permission of the Right Hon. the Earl of Mount Edgcumbe, the party will, an hour after arrival at Plymouth, proceed to Mount Edgcumbe, where, under the guidance of Mr. Richards, the head gardener there, the beautiful grounds and gardens of that famous estate will be inspected.—ANDREW HOPE, *Hon. Sec.*

— THE PEAR MIDGE.—It does not appear to be generally known that the abnormally large Pears met with at this season in the bunches or in trusses of bloom are infested with a number of white maggots, and owners sometimes are filled with dismay when I have advised picking and burning every one that can be reached in order to prevent the flies developing and causing mischief in the future. I have not followed up their life history, and would read with interest any remarks respecting them, and no doubt it would be a seasonable subject to others.—J. HIAM. [This paragraph was inadvertently omitted from our last issue.]

— VERONICA HULKEANA.—Although many of the shrubby Veronics will not live out of doors through a severe winter, the protection of a cold frame is sufficient to insure their safety. The little protection required warrants a few of the best a place in most gardens, as they come in nicely during spring to help to furnish the cool greenhouse—some in the capacity of foliage, and others as flowering plants. Of the latter the one under notice is the best. It is a native of New Zealand, and forms a loose-growing shrub about 2½ feet in height. The leaves are oblong, sometimes inclined to be ovate, with serrate margins, and are rather sparingly produced on the branches. The flowers are produced on terminal branched racemes, 8 inches in length; the lowest branches of the raceme are 2 inches in length, and carry about eighteen flowers; as they get nearer the apex they gradually become less, until at the top they are half an inch in length, and carry six flowers. The flowers are quarter of an inch across, and lilac in colour; they begin to open during March, and last from six to eight weeks if in a cool house. To grow them well, cuttings should be rooted in spring and kept growing all through the summer, with frequent stoppings until the end of July; they should then be left, to get the wood ripened for winter. Six or 7-inch pots are large enough to grow good plants in. They should be grown outside until the end of October.—D. K.

— ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on Wednesday afternoon, the 19th ult., at the rooms of the Royal Astronomical Society, Burlington House, Mr. E. Mawley, F.R.H.S., President, in the chair. Mr. F. Gaster of the Meteorological Office read a paper by himself and Mr. R. H. Scott, F.R.S., on the "Mean Monthly Temperatures of the British Isles." The authors dealt with the means of the daily minimum, average, and maximum temperatures for the various months of the year in the twenty-five years, 1871-95. They pointed out that there is a great difference between the amount of range of temperatures at the coast stations and that recorded inland. The range between January and July amounts to about 16° at coast stations, but to more than 23° at the inland stations. The contrast between the temperature of the air at inland and at coast stations at different times of the year is due to the following causes:—(1) The constant tendency of the sun to heat the surface of the earth; (2) the equally constant tendency of the earth to radiate its heat into space, both of these being modified greatly by the aqueous vapour and the clouds suspended in the atmosphere; (3) the fact that the solid portions of the earth absorb and reflect heat much more rapidly than the water; and (4) that while the ocean to the westward is of enormous size and great depth, the sea to the eastward is, comparatively speaking, limited in area and shallow, and separates the eastern shores of the British Islands from those of continental Europe by a small distance. A paper by Mr. C. V. Bellamy on the "Rainfall of Dominica, West Indies," was also read.

— CHURCHYARD BOTTOM WOOD, HIGHGATE.—We learn that towards the purchase of this wood as a public open space the Middlesex County Council, at a recent meeting, promised to give a sum not exceeding £5000, provided that Parliamentary powers are obtained to enable them to do so. The St. Pancras Vestry has also been approached by a deputation in support of a petition for a grant of £2000 towards the purchase of Churchyard Bottom Wood. A motion to refer the matter to the Parliamentary Committee was unanimously agreed to, and at the same time the Vestry expressed a desire that the wood should be preserved as an open space. We understand that since these meetings the promise of £1000 towards the purchase of this bit of old Middlesex woodland has been made by a lady who does not wish her name published.

— SUN ROSES.—These plants are very delightful, and it is a matter of surprise that they are so seldom seen. It is true the flowers are extremely fugacious, but then they are succeeded by others day after day for a considerable time, so that a good-sized bush is in the mornings of fine days covered with the small saucer-shaped flowers of various shades of pink, red, white, and yellow. The plants like a sunny position and a dry soil, but they should not be allowed to become too dry, as this would shorten the blooming period. They are very readily raised from seed, and a small packet will supply plants enough and to spare. Old plants do not remove satisfactorily. They are hardier than the Rock Cistus and flower earlier.

— SWAINSONIAS.—Different species of Swainsonia, particularly *S. Greyana* and *S. galegifolia*, which are largely grown for cut flowers now, are plants which are greatly dreaded by the stock growers in Australia. Chemical analysis does not show any toxic principle in the plants, and yet when sheep and other animals eat them they acquire a habit for them and will eat nothing else; their brains seem to become affected, they never fatten, and finally die. Sheep addicted to this habit are known as "Indigo eaters," and they separate from the flocks and wander about listlessly. A case is recorded where horses hobbled for the night at a place where Swainsonia was growing were difficult to catch the following morning, their eyes were staring out of their heads, and they pranced about against trees and stumps. Two out of nine died the second day after, and five others had to be left in the camp, for when driven they would suddenly stop, turn round and round for a time, then fall down, rise again and repeat the performance. No experiments as yet give any reason for the complicated effects which this forage has on stock, but there certainly is much testimony to the fact that it causes a sort of madness which induces creatures who feed upon it to attempt to climb trees or commit other eccentricities. Baron Mueller believed that Swainsonia possesses the deleterious properties attributed to it, and he publishes this view in the Transactions of the Royal Society of Victoria.—("Garden and Forest.")

BAMBOOS.

THE Bamboo of commerce, which, I believe, is botanically known as *Arundo donax*, is a grand subject for outdoor decoration. My experience of the plant is as follows:—Three years ago last March I bought a plant, and, as far as my memory serves me, one humble shilling was the medium of exchange. The produce of last summer's growth is twenty-three grand Reeds, averaging 10 feet in height; the tallest is 11 feet 6½ inches to the tip, and more than half were between that and 10 feet.

If it were not ridiculous I should say that the position was unsuitable, that the land is rather too "heavy;" but, on the other hand, it has perfect drainage, and also, as being within 7 feet of a large ditch, into which a small ditch runs, plenty of moisture. The waste water from a tub that is kept full (to soften in the sunshine) for use in frames is turned, the ditch ending at the Bamboo, through the roots of which the water passes.

I do not know the proper cultivation. My plan is, when the first new shoot appears above ground, to cut off all the previous year's growth; this prevents a certain untidy look in the summer, which is the only drawback to this most decorative family of plants. As my first shoot appeared to-day (May 20th), I should suggest that this is a good time to plant. I may further say that the shoots which come up early in the season are nearly as hard, when dry, as those we buy as flower sticks.—Y.

[*Arundo donax* is a strong-growing Reed. In Italy and the South of France the young shoots are eaten as Asparagus, the woody stems used as Vine supports and fishing rods, for which, and other purposes, they are imported to this country. *Bambusa arundinaria* is the common Bamboo, and is used for manifold purposes, including house building, ladder making, furniture, fishing rods, and, when split, into baskets, mats, and screens. *Arundo donax* imparts a tropical appearance to gardens, and the variegated form, *A. d. versicolor*, is regarded by many persons as particularly attractive, but is less hardy than the type.]

CYPRIPEDIUM VILLOSUM AUREUM.

COMPARED with this superb variety, the ordinary types of *C. villosum* are commonplace. In the first place the flowers are larger, they are much more brilliant in colouring, and owing to their greater substance last a good deal longer in good condition. The stems are green instead of purplish, the dorsal sepal has a distinct white margin, the body of the segment being bright golden yellow; petals and lip are both golden yellow externally, the lower part of the former having the usual shining brown tint. It thrives and blooms most profusely under the same conditions as the old *C. villosum*.

COELOGYNE CRISTATA (TRENTHAM VARIETY).

This is still in capital condition, the lovely sprays of pure white blossoms with lemon tinted lip being most useful for sprays and buttonholes now the ordinary varieties of *C. cristata* are over. The pseudo-bulbs are more ovate, not so round as those of the type, and occur at longer intervals upon the wiry rhizome. This necessitates more frequent repotting, or at any rate packing up with compost, as if the growths push far above the compost line they cannot so readily obtain sustenance from it. Otherwise the treatment is the same—a cool, moist, and shady atmosphere and regular moisture at the roots.

ONCIDIUM KRAMERIANUM.

This fine species has been in flower since January, and it is now pushing up fresh flower spikes. The blossoms occur singly in a long succession at the top of a long wiry peduncle that rises from the side of the pseudo-bulb. It is well known for its striking resemblance to a butterfly, the upper sepals taking the place of the antennæ of the insect, the lip and petals that of the wings. The colour is a bright golden yellow, with reddish brown markings. *O. kramerianum* requires plenty of heat and moisture, and a light sunny position to do it well.

The roots are not ambitious in pushing a long way from the centre of growth, consequently a large receptacle is unnecessary for them. It does admirably suspended from the roof on cork blocks, lightly dressed with living sphagnum moss, this being encouraged to grow as much as possible during the summer, and a little of it removed during the resting season. Small shallow pans are also suitable for it if filled nearly to the rim with clean crocks and a little peat and moss placed about the roots. It grows until late in the season, and every endeavour should be made to ripen the growth with the waning sun in autumn. *O. kramerianum* is a widely distributed plant in Central America, and was introduced in 1823.—H. R. R.

LYCASTE SKINNERI.

AN illustration of this beautiful plant, as grown in these gardens, having recently appeared in the pages of the *Journal of Horticulture*, a few notes on the culture of the plants, as practised here, may be of interest to some readers. This is, in my opinion, one of the most desirable of all Orchids, as the plants are of easy culture and require little heat. Our plants are grown in a span-roofed house, which is kept at a temperature of about 60°, with a rise of 10° by sun heat. The plant figured was grown in a 24-sized pot, and carried, when at its best, twenty-five fully expanded flowers, several of which were borne in pairs. It has three pseudo-bulbs, and leaves 2 feet in length. Although the species is very free flowering and lasts for several weeks in perfection, it is detrimental to the plant to leave the blooms on for a lengthy period, as by so doing it materially affects its flowering so well the following season.

The compost we find to suit them admirably consists of a mixture of fibrous peat and sphagnum, with a good sprinkling of silver sand, broken charcoal, and potsherds. The pots should be clean and well drained, copious supplies of water being necessary during the growing season, with an occasional application of weak liquid cow manure. The amount of water must be reduced in winter, although at no time should the plants be allowed to get dry at the roots. The flowers are very variable in colour, from a bluish white to a deep rose colour, those borne on the plant in question being of a bright rose colour, lip white, spotted with crimson. The most suitable time to pot the plants is soon after flowering, when they commence to make new growths, we having just completed ours.—H. T. M., Stoneleigh Abbey.

ORCHIDS AT SUMMERVILLE, DUMFRIES.

FOR some years Mr. James Davidson has been forming a nice collection, and a recent visit showed that his liking for these fascinating plants is being rewarded with considerable results. Newly imported plants are often purchased, and the interest these give when coming into flower for the first time is very great. This year a number of *Odontoglossums* are flowering for the first time, and some good things are appearing among them.

Last year a good form of *Odontoglossum crispum* came into bloom, and this year it is stronger and finer, giving a spike with thirteen flowers. It is of the true Pacho type, and the flower is of excellent form and well coloured. A very good form of *O. cirrhosum* with dark coffee-coloured blotches was also in flower, and an exceptionally fine variety of *O. Ruckerianum*. About 300 *Odontoglossums* are grown in all, other good varieties being a dark form of *O. cordatum*, a fine *O. vexillarium*, and one of *O. triumphans*. Several plants of *Cattleya citrina* were doing well and producing fine flowers. These have flowered for a few years, and show no sign of degeneration. There is also a very fine variety of *C. Mossiæ*, a capital dark-spotted *C. Schilleriana*, *C. Regnelli*, and a good variety of *C. intermedia*, with the lip a rich deep rosy purple. *Cattleya Skinneri* is also doing well.

Many *Cypripediums* are grown, among those in bloom being *niveum*, *Dominianum*, *Dayanum*, *Argus*, and a very dark form of *barbatum nigrum*. Other genera of the natural order are also well represented, and the progress made in a few years is very creditable to Mr. Davidson, who takes a strong interest in his Orchids, and attends personally to many of their requirements. Hybridising has been begun with *Dendrobiums*. The plants look well in general, the pseudo-bulbs being large and firm. Cleanliness and health prevail, ascribed largely to the use of the XL fumigating material.—A. S.

LÆLIA PURPURATA MALFORMED.

I HEREWITH send you a somewhat remarkable malformation in an Orchid, *Lælia purpurata*, which has, as you see, four lips. I thought it might prove interesting. Earlier in the season I had another peculiar deformity in a *L. purpurata*. The sepals and petals were normal, but attached to the base of the column where the lip is usually joined was a thread-like filament about 1½ inch in length, and to the end of this was attached a funnel-shaped structure for what should have been the lip. The colouring of it was the same as in a normal lip.—W. H. STEPHENS, *Prescot House, Stourbridge*.

[The abnormal flower of *Lælia purpurata* sent is just as described by our correspondent. A careful examination of the flower shows that the true labellum and the lateral sepals are almost perfectly normal, though the latter are more pointed than usual, and have not opened to their fullest extent. What we may term the spurious lips have taken the place of the dorsal sepal and the two petals, making four with the true lip. Another peculiarity not mentioned in our correspondent's letter is the fact that the column is quite transformed, and instead of the usual viscid stigma on the under side, and the pollen masses above, the latter are entirely absent, and the former is reproduced facing each of the abnormal segments. It would have been interesting if the pollen from another plant had been placed upon these to see whether the bloom possessed the power of fertilisation. The nectary was perfect, and the tubes could be easily traced to this, so probably it would, though, of course, no one would think of sowing the seed from such a bloom, or trying in any other way to perpetuate such a monstrosity.]

Botanists are fond of working out elaborate theories as to what causes this metamorphosis in Orchid flowers, but as a rule they have to content themselves with rather a vague idea of it. There can be no doubt that it is due in some cases to a physical derangement of the internal parts of the plant, and it would be well within the bounds of possibility to say that in this case the rudimentary parts of four, or at least three, blooms were present, the fact of three perfect stigmas pointing to this. The other parts of the flowers not developing, the whole became fused, as it were, into one, or should we say never became disunited, as they would do normally. But this, of course, is mere conjecture, as it must always be in cases of this description. Doubtless these malformations are sometimes caused by improper development, as, for instance, a badly ripened stem of *Dendrobium*. There is not time in this case for the flowers to form properly, and the advancing fluids push them out as they are, small, crude, and deformed. The best thing to do with a plant that produces this class of flower is to grow it as well as possible in the hope of inducing it to perfect its blossoms another season, but if it persists in pushing the deformities its best place would be on the rubbish heap.]

EXOCHORDA GRANDIFLORA.

AMONGST the many beautiful shrubs which flower in the spring and early summer, this must be accorded a prominent place. It has been known in this country for a considerable period, but is still rarely

blooming, it is surprising that such valuable qualities should remain generally neglected. This *Exochorda* (fig. 94) is diffuse in habit, and occasionally requires a little pruning to keep it in good form; and it can scarcely be surpassed for planting in shrubberies, as it rarely exceeds 9 feet in height, and flowers with great freedom during April

FIG. 94.—EXOCHORDA GRANDIFLORA.

seen even now. This is most unaccountable, as the merits of the shrub are of no ordinary character. When we consider its hardiness, combined with beautiful pure white flowers and a lengthened period of

and May. This charming shrub may be readily increased by layers or suckers, and thrives in ordinary garden soil. Where the ground is damp and cold, planting is best deferred till February or March.

REMEDIES WITH SULPHUR.

SULPHUR was first used in this country as an insecticide and fungicide. It formed an ingredient of nearly every composition advised by the old practitioners as a winter dressing for fruit trees, some laying stress on the use of "black" (sulphur vivum), and others on the employment of the "flowers." Even now the "black" has its advocates on the score of cheapness, less objectionableness to the eye, and for effectiveness, while some have become so accustomed to the "flowers" as to scarcely know of any other form.

Perhaps the "black" really has the most value for horticultural purposes from containing more or less sulphate of iron, and on that account may act more promptly on both insects and fungi than the "flowers," which appear to tell most by the fumes, and in slow degree corrosively by contact with either insects or fungi. But whether by contact or fumes, there is no question of both being destructive of external parasites, such as red spider and surface mould or mildew. True, red spider is only incommoded by the presence of sulphur on leaves when the sun is down or hidden by clouds, but as soon as the weather becomes hot there is a scent in the air that renders the red spider uncomfortable, and it gets "smaller by degrees and beautifully less."

Mildew likewise makes a sort of existence where sulphur is present when the weather is cold, but directly the sun shines powerfully and long it takes its departure. Thus the fumes are essential for banishing red spider and annihilating mildew. In thinking over this fact I have often wondered what effect the quarter million of cwts. of sulphur in the coal consumed in London in a year has on red spider and mildew in the metropolitan district. Certainly not much on red spider, if the defoliation of Limes and Elms be any criterion in a dry season; but I think it does something for mildew to the advantage of the cultivator, and probably other pests may suffer in consequence of the sulphur fumes belched forth by the numberless vertical shafts.

There is another side to this question—namely, its effect on vegetation. I noticed in your columns last year a quotation from an American paper advising the employment of sulphur on land as a preventive of Potato scab. I do not know what sort of scab they have in America, but one form in this country is greatly aggravated by the use of ashes, and the more sulphur in them the worse the tubers seem to be scabbed. Sulphur in drills when sowing Onion seed is said to prevent the maggot. Is it so? I have known grand specimen Heaths poisoned by dusting them with flowers of sulphur for killing mildew, and then thought there was danger in its use; while I have not found any record of sulphur being advantageously used to soil as regards the health of plants or crops.

Then there are the fumes. I have seen Roses injured by the continued use of flowers of sulphur for keeping down mildew; also golden coloured Muscat Grapes turned steel blue by fumes of sulphur emanating from it on hot-water pipes. The foliage of Cucumbers, Melons, Tomatoes, and Vines have been hardened by fumes of sulphur from hot-water pipes, Cucumbers stunted and crooked, and Melons cracked; while Tomatoes have been scorched and scarred by sulphur fumes. Adding the Grapes to the picture, my consternation at the effects of sulphur was complete.

That is the dark side; it is darker when sulphur is burned in any structure both for red spider, mildew, and the plants or crops. There is the bright side—red spider, white fly, and the mildew killed; and the crops saved by the timely and judicious use of sulphur, both on the plants and fumes given off by it in hot-water pipes when heated to between 170° and 200°. Some go farther, and aver that sulphur fumes drive out or prevent the coming in of fungal germs, producing internal diseases in crops. That may be, for they all gain entrance to the plants they infest from without—besides, there is the heat and comparatively drier atmosphere, in which the parasites may not be able to germinate. All this shows a bright side in theory and in practice; but where is the proof? What mean the reserve plants, almost as many in some cases as those set out, for many good casualties? Why all this resource if the sulphur fumes make all safe? The germs seem to defy the sulphur fumes, and make such havoc as to render a strong reserve imperative; therefore we may dismiss this phase as chimerical, and are left in the old slough of uncertainty and bewilderment.

The most, therefore, that can be said for sulphur is that of its being useful for killing certain pests, and at the same time more or less inimical to vegetable life in whatever form applied; whether to the roots or tops of plants, its action is to some extent detrimental. This property sulphur has, in common with many other preventive and repressive articles, and though it may be difficult to otherwise act, it is time that attention be given to such substances as would at the same time profit the plant—cleansing, refreshing, and invigorating it, as does the rain.

Sulphur is applied in two ways—insoluble and soluble, simple or compound. There is—1, The flowers of sulphur, and this is dusted on. A bellows apparatus is best for applying it, and the less the better, for it is not the quantity but the method of administration that effects the object in view, and remember that prevention is better than cure, therefore use the sulphur betimes, and repeat as necessary for the destruction of mildew.

2, The liquid application consists in forming either black sulphur or the flowers of sulphur into a paste with skim milk, using 2 ozs. of sulphur to a 4-gallon watering can of soft water, and keep it mixed by alternating syringing into the vessel and on the infested plants. This also is to be repeated as required for mildew.

3, Sulphide made by slacking 1 lb. of quicklime in a copper, forming

a thin whitewash with a gallon of water, then add 1 lb. flowers of sulphur, mix thoroughly, and boil a quarter of an hour, keeping it stirred all the time. Let it settle and cool, then pour off the liquor, bottle, and keep it well corked in a dark place. Use 1 pint to 12 gallons of water, or a quarter of a pint to 3 gallons. This is for mildew, and if used on Vines must be syringed off in a quarter of an hour. If for insects or mites, either red spider or gall mites, add 2 ozs. of softsoap to each gallon, thoroughly dissolving before adding the bisulphide of calcium. The sulphide has an unpleasant smell, and discolours paint, therefore discrimination must be exercised in its use, but both pass off.

4, Sulphur fumes for mildew, red spider, and white fly are had by forming flowers of sulphur into a cream with skim milk, and applying with a brush to the hot-water pipes heated to 160° or more and the house closed, keeping the pipes hot about an hour whilst and after the mixture is applied, then allow the heat to fall to the ordinary temperature.

Now remember that if sulphur fumes—a sort of sulphurous gas—are effective against mildew, red spider, and white fly they require care, for when the pipes are highly heated, and the fumes are long continued, there is danger of the foliage and the fruit being hardened so as not to develop well afterwards, Grapes often being rusted or discoloured, and the effect is similar on other fruits; at least, such has been the experience of—LUCIFER.

CYTISUS AND GENISTAS.

As several of our most beautiful hardy flowering shrubs are included in one or other of these genera it may not be out of place to draw attention to a few of the best for general garden work. In the "Kew Hand List of Trees and Shrubs" thirteen good species of Genistas and fifteen of Cytisuses are recorded, together with a selection of the most distinct varieties of those species. All are to be found in the collection of leguminous plants near the pagoda at Kew, whole beds being made up of those sorts which are most suitable for extensive planting.

CYTISUSES.

The earliest to flower of this genus is *C. biflorus*, a yellow flowered Eastern European species. The flowers are usually produced in pairs (sometimes, however, in groups of three or four) all along the previous year's growth. In mild weather the first flowers are produced early in April. To be successful with this it is necessary to renew the stock from seeds every four or five years, as the plants often deteriorate after that length of time.

Closely following this comes *C. præcox*, a well-known hybrid with sulphur coloured flowers. It is a hybrid between *C. albus* and *C. purgans*, and combines the good qualities of both. Besides being reckoned as one of the best Cytisus, this can also be classed as one of the very best spring flowering shrubs. A compact growing species is *C. purgans* with its deep yellow flowers. At Kew it forms bushes 1½ to 2 feet in height by the same in width. It commences to flower about the end of April. *C. albus*, like the preceding, is a European plant. It is, however, a taller grower with a freer and more graceful habit, and produces pure white flowers in great profusion.

C. scoparius is one of the handsomest of our native shrubs, and can be grown in almost any soil or situation. It, however, well repays a little extra care, as it produces a wealth of rich yellow flowers excelled by no other shrub. The variety *C. scoparius Andreanus*, which has the two wing petals of a rich brown colour, is now well known, and needs little recommendation, as when once seen in flower it is always remembered. If seeds of this are sown about 30 per cent. will be found to come true. *C. scoparius* var. *pendula* is a fine variety, but rather scarce. The flowers are larger than those of the type, and produced on pendent branches. There is also a variety with cream coloured flowers known as "Moonlight Broom" which is well worth growing.

C. purpureus is interesting if only on account of its flowers differing so widely in colour from any other species. It is, however, a very good flowering plant. Growing about 15 inches in height, and having pendulous branches it makes a good plant for growing on rockwork. The graceful hanging branches looking particularly fine when wreathed with rosy purple flowers and light green foliage. It is a native of Eastern Europe. *C. Ardoini* is a charming plant, but little known. It is a native of the Maritime Alps, and grows only a few inches in height. The flowers are very freely produced, and bright yellow in colour. It looks at its best when growing on a rockery.

C. Kewensis is a beautiful hybrid between *C. Ardoini* and *C. albus*. It is a prostrate grower, and will make a fine plant for rockeries. The flowers are cream coloured, and very freely produced. They open early in May. *C. nigricans* flowers about the end of June. The blooms are produced on upright terminal racemes 6 to 8 inches in length on present season's growth. The leaves are dark green, much darker than in any other species. Altogether this is a very distinct and interesting plant. It should be cut back well when young, otherwise it makes a leggy plant.

GENISTAS.

For all practical purposes one name would do for the two genera, very little difference existing. The most noticeable variation is that in the Cytisus the leaves are usually ternate, while those of the Genista are simple. Of the Genistas the following are the best:—

G. æthnensis from Sicily is a tall-growing species, attaining a height

of 12 to 15 feet. For grace of habit this cannot be excelled by any other. The branches are long, thin, and pendulous, usually destitute of leaves, but during July literally covered with bright golden flowers. *G. virgata*, which also attains a height of 12 to 14 feet, and a width equalling the height, is an upright growing species from Madeira. It does well in sandy soil, and always flowers freely. It is one of the best.

G. cinerea is one of the latest to flower. It makes a bush 3 to 4 feet high, with long thin branches. The flowers are yellow, and produced late in July. *G. hispanica* forms a dense bush about 2 feet high and 2 to 3 feet in diameter each way. The growths are short and spiny, the flowers deep yellow, and produced in short upright racemes from the points of the young growths about the beginning of June. So freely does this species flower that when fully expanded little or no growth is to be seen. It is a native of South-west Europe. *G. sagittalis* is a dwarf-growing, free-flowering species. It is a very interesting plant, differing from any of the other *Genistas* by the membranous margins of the stems. The flowers are produced on upright terminal racemes from the current season's growth. They are deep yellow in colour. When in flower the plant does not exceed 8 inches in height, consequently it is a good plant for rockwork, or for a carpet to a bed of taller plants. *G. pilosa* and *G. tinctoria* are both good flowering species, and well worth growing. A prostrate form of *G. tinctoria*, having double flowers, is very pretty, and ought to be found in every garden.

To grow these plants well they should be cut back (after flowering in the case of those which flower on old wood, and in spring in the case of those which flower on young wood) for the first two or three years, so as to get a good foundation for the plant. A stock of young plants should be raised every few years to replace exhausted ones. It is best to propagate all the species from seeds and all the varieties from cuttings, as they do much better from cuttings or seeds than when grafted. Cuttings root best if put into a cold frame in sandy soil in August and kept close all through the winter. They will then be found to be rooted about the end of March.

If possible they should be planted in their permanent quarters when a year old, big plants moving badly. If there is plenty of room at disposal it is advisable to grow all the best sorts in 5-inch pots until planted out for good. When planting care should be taken to make the soil firm round the collars, otherwise the least wind blows them about. All growths should be kept pinched back the first year to a few buds in order to obtain a good foundation.—W. D.

RAISING SPRING-FLOWERING PLANTS.

THE cultivator must always be looking forward. A good display of bloom in spring is only secured by sowing at a suitable time, so that the plants may have time to grow to a useful size, and become strengthened before activity ceases for the season. Plants raised late are and frequently remain weakly, seldom flowering well. There is also the probability of losing them in the winter, especially in unsuitable soils and climates. These are, therefore, strong grounds for not deferring the work. In addition favourable germination is obtained with less attention, and a sufficiently bushy with a sturdy habit is developed, while roots of a fibrous character are more abundantly produced. It follows from the successful carrying out of these preliminaries that there will be a greater certainty of ultimate success.

The preparation of the ground for sowing the seed should be effective. Rich soil is not requisite, though it ought not to be poor and shallow. If moderately fertile, moist, and partially shaded it will be suitable. Dig it well over, pulverising the whole to a fine tilth. A friable surface being secured the seed may be sown, but in dry weather it is preferable to apply water with a roset can before sowing, so that suitable moisture, so essential to germination, may be present. It is chiefly necessary to apply water when the soil is comparatively dry to a considerable depth, also in the prospect of continued dry weather. Sowing the seed first and watering immediately afterwards is not a good method as a rule. The advantage of watering prior to sowing is that the moisture applied is retained by the layers of dry soil used for covering the seed. A little shade in the hottest weather may be given, which frequently prevents the necessity of giving water until the seed germinates.

Seeds which may be sown now are Wallflowers, Primroses, Polyanthuses, Forget-me-nots, Pansies, and Violas. The first three named need the longest growing period, and should be sown as soon as possible, so that good plants may be ready by the autumn. The method of sowing may be broadcast; there is no special advantage in sowing in drills. The young plants in all cases are improved by transplanting unless they happen to be sown so thinly that the young plants do not touch; but this can rarely be the case without the disadvantage of utilising more ground than is absolutely essential. Therefore, sow liberally, though not lavishly and thickly; but transplant when the seedlings are large enough to handle readily.

The middle or end of July is a suitable period to transplant Wallflowers, Primroses, and Polyanthuses. The two latter, of course, are only small when ready for transplanting. They may be placed out with a dibbler or trowel on a plot of ground made fine and smooth on the north side of a wall or hedge. If deficient in humic matter add a little leaf soil or manure. Give the seedlings a space of about 3 inches from each other. Keep watered in dry weather until established, after which little will be needed.

Wallflowers, if transplanted in dry weather, are best placed out in drills, watering each row of plants as they are inserted. First prepare the ground by digging and manuring. Do not apply manure too freely.

Cut a straight, shallow trench with the spade. Insert the plants along it with their roots spread out at the bottom, covering them with a layer of soil. Give a soaking of water, then fill in the remainder of soil, proceeding to take out and plant another trench in the same way about 5 or 6 inches from the first. The plants may be 4 inches asunder. The advantages of this method in dry weather are very obvious. The plants appreciate it by rapidly taking hold of the soil without repeated waterings. When the soil and weather are moist the planting may, perhaps, be more expeditiously done with the trowel.

Forget-me-nots, if sown thinly in moist fertile soil, in any shady position, do not need transplanting. In autumn they can be lifted and planted direct to the position wanted. Pansies and Violas may be sown in drills or broadcast early in July. Should the seedlings come up thickly early thinning may be resorted to, pricking out the surplus seedlings. This will afford the whole of them the means of strengthening and becoming suitable sized plants for transference to a permanent position in autumn. Fairly strong plants winter well and bloom freely the following season.—E. D. S.

SPRING BEDDING AT EATON HALL.

THE gorgeous display of spring bedding at this princely establishment of His Grace the Duke of Westminster has this year been on a magnificent scale, and beautiful beyond description. I recently had the pleasure of making a tour of the gardens, where the effect of a master hand is everywhere visible, not in any one department alone, but in all departments, from the beautiful Orchid houses to the vegetable quarters.

But it was the spring bedding I went specially to see and of which I wish to speak here. What struck me very forcibly was the limited variety of plants that Mr. Barnes had employed to secure such a beautiful display, for single Wallflowers in separate shades and late-flowering Tulips in distinct varieties contributed chiefly in making the effect. Wallflowers appear to have done well everywhere this spring, but here they were exceptionally good, the different sorts being Dickson's Golden Beauty, Selected Blood Red, Belvoir Castle, Primrose Dame, and Ruby Gem, the latter being a comparatively new variety which is sure to be more extensively grown when better known. Its beautiful rich ruby-coloured flowers contrast nicely with the yellow shades. Of Tulips such varieties as elegans Picotee or Maiden's Blush, Golden Eagle, Bouton d'Or, Gesneriana major, Blushing Bride, and retroflexa, were used abundantly, the general favourite, however, being the first-named variety.

Aubrietias græca, Leichtlini, and purpurea, together with Primula cortusoides, played a minor part in the way of edgings, each being very effective in its way. Upon the occasion of the recent visit of their Royal Highnesses the Prince and Princess of Wales to Eaton, I understand they took particular notice of the spring bedding generally, but made special mention of the Wallflowers and Tulips, and admired the method adopted to secure such beautiful effects.

In passing hurriedly through the houses, I could not help stopping to look at the splendid collection of pot Carnations, numbering about 5000, almost every plant being thickly set with bloom buds, but none yet showing colour, save an odd plant of the beautiful yellow Miss A. Campbell. Mr. Barnes anticipates these will be at their best from the middle to the end of June, at which time the Jubilee rejoicings will be in full swing, when such flowers will be largely in demand for decorative purposes.—GEORGE PAXTON.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNIVERSARY DINNER.

MEMBERS, friends, and patrons of this Institution met at the Whitehall Rooms, Hotel Metropole, on the evening of the 26th ult., to celebrate the fifty-eighth anniversary festival. The chair was taken by Lord Rothschild, who was supported by Sir Trevor Lawrence, Bart., Lord Wandsworth, Rev. W. Wilks, M.A., and H. J. Veitch, Esq. Included in the assembly were Messrs. G. A. Dickson, P. Crowley, N. Sherwood, W. H. Protheroe, G. F. Morris, Algernon Gilliatt, C. Czarnikow, N. L. Cohen, W. Nutting, J. Laing, H. J. Cutbush, J. H. Veitch, G. Banyard, G. Monroe, Geo. Cutbush, R. Sydenham, R. M. Hogg, S. M. Segar, F. Lane, W. Icton, J. Jeffries, H. Turner, Geo. May, P. E. Kay, W. Poupert, T. Rochford, Geo. Paul, Jas. O'Brien, J. Godseff, A. W. G. Weeks, T. F. Rivers, G. Gordon, G. Wythes, N. F. Barnes, P. Blair, J. Douglas, and Jas. Hudson.

After the health of her Most Gracious Majesty the Queen had been proposed by the Chairman, and drunk with musical honours, followed by that of their Royal Highnesses the Prince and Princess of Wales, with the rest of the Royal Family, Lord Rothschild rose, amid cheering, to propose the toast of the evening—"Prosperity to the Gardeners' Royal Benevolent Institution," and in course of his brief speech said, "I have been told that quite lately, on an occasion analogous to the present one, he who proposed the toast of the evening began his speech by excusing himself for his appearance there, and by reminding those who were trying to listen to him, that they well knew of his dislike to public dinners. Now I shall not tell you that I dislike the dinner, nor do I dislike the Gardeners' Royal Benevolent Institution (cheers), and I would ask those who, like myself, receive pleasure from their gardens and their flowers who are present this evening,

to help the Treasurer, Mr. Veitch, by their subscriptions, not only to pay annuities to old gardeners, but also to the widows of gardeners. This Society is co-existent with the reign of her Majesty the Queen, so that we might be celebrating its Diamond Jubilee (cheers). If those who are present here will cast their memories back they will not fail to recognise that during the last sixty years horticulture has made tremendous strides. The extending of the Empire, the steamship, and the telegraph have all in their way helped us to get plants from all parts of the world. We have the beautiful Water Lily, *Victoria regia*, named after Her Majesty, and in the Show which has to-day opened in the Temple Gardens there is a lovely Orchid, which bears the name of the Princess of Wales, and there are many others, the presence of which we owe to the last sixty years. No doubt when our successors meet here sixty years hence they will gloat over the strides made and the plants introduced during that time as we do now, and I hope they will be able to look back on the last sixty years with as much pleasure and pride as we can to-night (cheers). Gentlemen, I will conclude by asking you to drink with me to the prosperity of the Gardeners' Royal Benevolent Institution, coupling with it the name of the Treasurer, Mr. Harry J. Veitch."

Mr. Veitch in replying heartily thanked Lord Rothschild for the honour he had conferred on them by his presence on that occasion, adding that they were all aware of his Lordship's fondness of gardening, and his advocacy for the Institution. He did not propose wearying them with details, as information would be gladly given to anyone who care to have. They had, however, at the beginning of this year 161 pensioners, the largest number they had had at any one time, half of which were men, and half women. Two of these have passed away since the election, both residing in the same county, and he (Mr. Veitch) felt sure that it would be a comfort to those present to know that the declining years of their lives were made happy in the knowledge that not only were they provided for, but also the widows they left behind them.

Up to 1885 they had paid £16 a year to men, and £12 to women, but then the amounts had been increased to £20 for men and £16 for women. The sum of £3000 per annum was required to carry on the work. The Secretary's salary and office expenses were practically the only cost they had, as they had no expensive buildings to maintain and keep in repair. Since the Institution was inaugurated £71,000 had been paid. Sometimes the executive exercised its power in making special grants, and not long ago they received a letter from an old woman whose husband's only means of existence for years had been the annual £20 received from the Institution, begging for a little further help so that the parish would not have to bury her husband. He, Mr. Veitch, felt sure that those present would agree with the action of the Committee in sending her £5.

They have a great many applications for relief, some of whom have been trying for four or five years, and next year they will have many more. In drawing comparison between the year 1851, when Her Majesty became patron of the Institution, the Treasurer stated that in 1851 there were thirty-five pensioners; this year there are 161. Then fifteen candidates were elected against fifty-one this year, and the highest number of votes then was 480; this year the highest number is over 3000. In 1851 the amount paid in pensions was £512, against the sum of over £3000 now paid. At the time he had chosen the invested funds were £2250, now they are £26700. The Committee, continued Mr. Veitch, had decided to celebrate the Diamond Jubilee by raising what is called the Victorian Era Fund, by the aid of which they proposed sending the sum of £5 to each unsuccessful candidate. They asked for the sum of £8000, which would be invested, and the interest devoted to giving temporary relief to unsuccessful candidates who have subscribed to the Institution, and would receive assistance according to the amount they had paid in.

Mr. Veitch reminded them that the fund remained open till the end of the year, and though he well knew that Jubilee claims affected everyone, yet he had hoped that the amount would be raised. He could not close without reference to two friends of the Institution who had passed away since the last anniversary dinner. One (the late Mr. James Webber) an able member of the Committee, and to whose good management much of their success was due; the other was his dear friend Dr. Hogg, a man who was ever ready to help a worthy cause. The late Doctor was one of the Trustees, and he was pleased to tell them that in his stead the Hon. Walter Rothschild, son of the Chairman, had kindly consented to act. The family had long been connected with these functions, and in 1884, when Mr. Leopold Rothschild occupied the chair, they had a record subscription list of £3400. He thanked his Lordship again for his presence, and hoped in honour of it this evening would be a record one for the Institution. (Loud cheers.)

Mr. G. A. Dickson gave the toast of "Gardening," and in doing so spoke of the occupation as one which gave pleasure to all, rich and poor alike. He further referred to the strides that had been made during the reign of Her Majesty, evidence of which could be seen in the show in the Temple Gardens. The Royal Horticultural Society, said Mr. Dickson, had had its ups and downs, and now he was glad to say it was up. Gardeners also had their ups and downs, and though "Hope deferred maketh the heart sick," they are a class of men endowed with patience, and always do what they can to help themselves and those about them. He would couple with the toast the name of Sir Trevor Lawrence, and he knew of no one more capable of acknowledging it, being, as they knew, a true patron of gardening and President of the Royal Horticultural Society.

Sir Trevor, in reply, said he had been connected with gardening all his life, and remembered as a boy knowing the names of many plants,

and when he took visitors round his mother's garden he thought he knew a great deal on account of this, but since he has found that he knew very little. He had also had some experience in gardening, and remembered going into the valleys in India and bringing home some branches covered with *Saccolabium*—but, alas! the goat of a neighbour came and eat them. We owe, continued Sir Trevor, a debt to gardeners, and a great one, as we ask them to cultivate plants from all parts of the world, and though the burden is heavy it is one which they discharge well. In no country in the world has more interest and intelligence been brought to bear on horticulture, with the result that our country smiles like a garden. In concluding his speech Sir Trevor asked those present to drink the health of the Chairman, adding a few remarks on the interest which he (Lord Rothschild) and other members of the noted family took in all things appertaining to gardening.

Lord Rothschild thanked those present for the kind and hearty manner in which they had received the toast, and congratulated them on the subscription list, which he was pleased to see amounted to over £5000 (cheers).

Mr. G. J. Ingram then read out the names of the chief subscribers, which included Lord Rothschild (Chairman), £50; Messrs. Rothschild and Son, £210; H. J. Veitch, £250; Jas. Veitch & Sons, £250; J. G. Veitch, £250; J. H. Veitch, £250; N. Sherwood, £500; P. Crowley, £15 15s.; W. E. Gumb'eton, £52 10s.; T. W. Webley, £26 5s.; J. Sweet, £25; J. Rochford, £25; Cecil Rhodes, £25; Arthur Sutton, £100; H. Low & Co., £52 10s.; A. Waterer, £40; W. Robinson, £52 10s.; G. Bunyard & Co., £10 10s.; R. M. Hogg, £20; Lord Wandsworth, £20; J. C. Geiseler, £12 12s.; J. Jennings, £92 18s.; W. Iceton, £11 11s.; Duke of Westminster, £100; Baron Schröder, £200; Geo. Monro, £100; collected at Mr. Monro's table, £29 8s.; C. Czarnikow, £100; Thames Bank Iron Co., £21; Protheroe & Morris, £21; Wills & Segar, £10 10s.; G. H. Richards, £10 10s.; Worcester Auxiliary, £68; Wolverhampton Auxiliary, £50; J. Weeks & Co., £10 10s.; Sir T. Lawrence, £10 10s.; F. Debenham, £10 10s.; W. Farr, £12 12s.; W. Howe, £10 10s.; F. Sander, £15 15s.; Bailey Wadds, £35; F. Harris, £14 14s.; W. J. Stacey, £12; Exeter Auxiliary, £8 8s.; G. Burt, £12; Miss Parker, £5; J. Herrett, £21; with numerous other sums already acknowledged.

The health of the Secretary was proposed by Sir Trevor Lawrence, to which Mr. G. J. Ingram made an appropriate response. Music, instrumental and vocal, was supplied under the direction of Mr. George Ashton.

THE PEAR-GALL GNAT.

OF all the destructive enemies of the Pear this is the most speedy and certain, as well as singularly disastrous. Happily it is but local in this country, and mainly has home in the south-western counties of England. It, however, may at times be found in places over a wide extent of country, and appears to be unusually prevalent this season.

The Pear midge, or Pear-gall gnat (*Diplosis pyrivora*, Riley), is decidedly British, the well-known *Sciara pyri* of older times, and of recent *Diplosis nigra*. It was first noticed in Connecticut, United States of America, about 1877, hence must have been an introduction from the mother country, as it has been known in England for centuries. From Connecticut it spread into a number of neighbouring States, and has become in many localities the most destructive enemy of the Pear. Thus, whether at home or abroad, the British Pear-gall gnat maintains its thoroughly national characteristics, and acts in a certain business-like manner; yet has its likes and dislikes, for both in this country and elsewhere it prefers the roundish or Doyenné-shaped to the pyriform fruited varieties of Pear, and is more prevalent in valleys than on hills.

The effect of an attack on Pears by the Pear midge is to produce an abnormal swelling of the young fruits, causing them to have an ill-shapen appearance. This, however, does not always follow, for the affected fruits sometimes swell evenly. One of such Pears is shown in the illustration, fig. 95, at A, natural size. The observant cultivator notices the rapid swelling of such fruit, and unable to account for the speedy growth, rightly attributes it to an alien cause. This leads to examination, and on cutting an affected Pear in half longitudinally, it is found black at core, and in the cavity or gall there formed are seen small whitish maggots (B at a). These and the condition of the fruit convince the examiner of the destructive nature of the pest, and while some know, others desire information respecting its life-history, with mode of prevention and remedy.

The Pear-gall gnat is a small two-winged fly, intermediate in form between a midge and a gnat—that is, the wings resemble a midge, and the body and legs a gnat. Its wings are blackish, so is the frontal part of the body, but the abdomen is paler or slate coloured, altogether a pretty little fly. The female possesses an ovipositor. Eggs white, just or scarcely visible. Larva at first whitish, soon turning orange or reddish; length one-sixth of an inch when full grown, then yellow in colour, with a brown, horny breastbone on the under side just behind the head. The body tapers towards both ends, most pointed in front, with segments well defined, and when removed from the infested fruit moves about rapidly, banding quite double by drawing the tail forward until it touches the head, and then jerking or springing upward and outward several inches at a time. Pupa yellowish brown, with darker markings; legs folded under the body.

The Pear-gall gnats appear in the early spring, commonly before the flowers of the Pear trees open, and remain about ten days. After pairing the female deposits her eggs inside the blossom envelope when the Pear flower has opened sufficiently for the insertion of her long ovipositor. The eggs are placed at the base of the blossom, and sometimes in the

neck of the ovary, and in three or four days the eggs hatch into tiny maggots in the ovary of the embryo fruit, where they feed upon the growing tissues, which, by the constant gnawing and rasping and irritation, incites undue growth of tissue, and this being outward from the exciting cause a gall is the consequence. The effect is to destroy the core and ovules, and the maggots continue until full-fed. This takes place early in June in forward seasons, when decay follows, and the infested fruit either falls or cracks and the maggots emerge, dropping to the ground. They enter the soil an inch or two, and after resting awhile make oval cocoons of silken threads mixed with particles of earth. In these cocoons they remain quite content, and apparently unchanged, until the Pear blossom buds commence swelling, so timing the entrance on the pupæ state, which takes about a month, that they will appear in perfect form—male and female—by the time the Pear blossoms are in good colour, and have nothing to do but await the expansion of the petals for inserting the eggs. These are seldom less than a dozen, and often many more in number, which means a corresponding number of maggots, so that there is no wonder they make such speedy work of the Pears.

The only stages at which the Pear-gall gnat can well be proceeded against are—1, When the flies appear. The practice of catching them on strips of tin about a foot long and 3 inches wide, smeared on both sides with a substance formed of resin and sweet oil melted together, is very old and excellent, especially for choice varieties of Pears, as such trees are low, and the tin traps—shining like gold—can be affixed on a level with or just above or outside the blossoms. The traps must be in position just before the flowers unfold, continuing for about a fortnight.

Another plan is to spray the trees just before the blossoms open with soluble petroleum, again when the blossom is well out, and a third time after the petals fall. The soluble petroleum does not affect the setting, but care must be taken to apply the second dressing before the pollen cases burst. It is prudent to first try the effect of the preparation on a few cut sprays placed in water, using an atomiser, and note the effects. Such "fine" smelling substances as formalin and spidacide are almost certain to drive away such pests as the one under consideration, and have the advantage of being safe to use. They are mentioned for experiment.

2, As soon as the Pear blossom has set, or in the earliest larval stage of the insect, promptly use an insecticide when the petals drop and get it into the eye of the fruit. This will cure the maggots, but not the Pears, for when their ovules are damaged or destroyed the flesh is of very little use.

3, While the maggots are in the fruit, the removal of the affected Pears and burning them never fails. It is the catch 'em and kill 'em practice, too slow for adoption on a large scale, but practicable and serviceable in the case of small trees in gardens; but fruit tree pests will never be banished until the neglected orchards are taken in hand by competent pathologists.

4, When the larvæ have left the fruit, which takes place about the middle of June, later in backward seasons, supply a dressing of best quality kainit—10 cwt. per acre, 7 lbs. per rod, or 4 ozs. (rather less) per square yard just after rain. The salt will be dissolved by the soil moisture, and the solution coming into contact with larvæ destroys them. In the case of cultivated land the kainit may be lightly pointed in.

The most hateful thing to pests is good cultural methods that make for their disturbance and eradication. But when the orchard so treated adjoins another that knows neither soil cultivation nor essential top-management all the labour will be in vain, as the Pear-gall gnats are bound to find their way from the neglected to the cultivated trees.—G. ABBEY.

ROYAL NATIONAL TULIP SOCIETY.

NORTHERN SECTION.

THE annual exhibition of this Society was held at the Free Library, Middleton, near Manchester, on Wednesday, May 26th. The date fixed did not suit several of the northern growers particularly well, but it enabled some of the early growers, among whom may be named the Rev. F. D. Horner and Mr. Haynes, who are usually unable to be present, to exhibit. Considering the weather we have had the flowers shown were of excellent quality, particularly in the feathered classes. Other notable features of the show were the excellent seedlings, mostly breeders, shown by the Rev. F. D. Horner, and a collection of rectified seedlings exhibited by Mr. Jas. Thurstan of Cannock. Mr. Horner's breeders showed that he had effected great improvements in form and purity, and his feathered Charm, and Miranda, and flamed Magpie, all byblœmens, were very promising flowers. Mr. Thurstan's seedlings were of all three classes, and showed that he has obtained many new varieties of great refinement and merit. Some of the older varieties were in first-rate form. It was pleasant to see George Hayward, Duke of Devonshire, and Victoria Regina well feathered again. In flamed flowers Sir Joseph Paxton is still supreme, but Samuel Barlow is a grand companion to the older variety, and a bloom of the latter variety would have had the premier this year had not it have been injured while growing. Breeders, with the exception of Mr. Horner's, were not up to the usual quality, being too young and bud-like.

This year the Judges were selected from among the exhibitors, and although there was no complaint of the judging it is unlikely that the experiment will be repeated, as it was found that the task of staging flowers and also judging was rather too great for comfort. There was a very stiff competition for the silver cup for the best twelve rectified

Tulips, which the Judges finally awarded to Mr. James W. Bentley of Stakehill near Manchester, who was closely followed by the Rev. F. D. Horner and Mr. C. W. Needham. This is the fourth year in succession that Mr. Bentley has won the first in the class for twelve rectified Tulips at this Show. The premier feathered flower was Mr. Needham's Wm. Annibal, a very correct flower, lightly feathered with red on a pale yellow ground. The premier flamed was Mr. Horner's Sir Joseph Paxton, shown in Class 8. The same gentleman also secured the prize for the best breeder with his seedling Fairy Ring, which was everything one could expect in shape, colour, and purity. Following is a complete list of the awards:—

Class 1. *Twelve dissimilar Tulips, two feathered and two flamed in each class.*—First, Mr. J. W. Bentley, Stakehill House, Middleton, with Lord F. Cavendish and John Mills, feathered bizarres; Sir Joseph Paxton and Samuel Barlow, flamed bizarres; Modesty and Julia Farnese, feathered roses; Mabel and Annie M'Gregor, flamed roses; Trip to Stockport and Bessie, feathered byblœmens; and Chancellor and Talisman, flamed byblœmens. Second, Rev. F. D. Horner, Burton-in-Lonsdale, with Sir Joseph Paxton and Masterpiece, feathered bizarres; Sir Joseph Paxton and Samuel Barlow, flamed bizarres; Mrs. Atkin and Mabel, feathered roses; Mabel and Annie M'Gregor, flamed roses; Mrs. Cooper and Miranda, feathered byblœmens; Duchess of Sutherland and Magpie, flamed byblœmens. Third, Mr. C. W. Needham, Royton, with Wm. Annibal and George Hayward, feathered bizarres; Sir Joseph Paxton and Dr. Hardy, flamed bizarres; Modesty and Miss Edwards, feathered roses; Aglaia and Mabel, flamed roses; Bessie and Elizabeth Pegg, feathered byblœmens; Talisman and Chancellor, flamed byblœmens. Fourth,

FIG. 95.—GALLED PEAR AND ITS CAUSE.

A, affected fruit (natural size). B, section of same, showing: a, gall with maggots. C, Pear gall gnat; D, male (natural size); E, female as seen depositing eggs (magnified); showing D, ovipositor; F, eggs (natural size and magnified); G, young larva, ditto; H, looping gait of maggot, ditto; I, full grown larva, ditto; J, cocoon (natural size); K, section of same showing maggot at rest; L, pupa (natural size and magnified).

Mr. A. Moorhouse, Wakefield, with Sir Joseph Paxton and Wm. Wilson, feathered bizarres; Sir Joseph Paxton and Wm. Wilson, flamed bizarres; Modesty and Industry, feathered roses; Aglaia and Annie M'Gregor, flamed roses; Trip to Stockport and Mrs. Hepworth, feathered byblœmens; Talisman and Bessie, flamed byblœmens. Fifth, Mr. T. Haynes, Warwick, with Sir Joseph Paxton and George Hayward, feathered bizarres; Sir Joseph Paxton and Dr. Hardy, flamed bizarres; Mabel and Alice, feathered roses; Mabel and Aglaia, flamed roses; Violet Amiable and Adonis, feathered byblœmens; Duchess of Sutherland and Beauty of Litchurch, flamed byblœmens.

Class 2. *Six dissimilar Tulips, one feathered and one flamed of each class.*—First, Rev. F. D. Horner, with Ben, feathered, and Saml. Barlow, flamed bizarres; Modesty, feathered, and Mabel, flamed roses; Charm, feathered, and Duchess of Sutherland, flamed byblœmens. Second, Mr. Bentley, with General Grant, feathered, and Dr. Hardy, flamed bizarre; Modesty, feathered, and Mabel, flamed roses; Camp's Seedling, feathered, and Talisman, flamed byblœmens. Third, Mr. Needham, with Sir Joseph Paxton, feathered, and flamed bizarres; Modesty, feathered, and Triomphe Royale, flamed roses; Elizabeth Pegg, feathered, and Talisman, flamed byblœmens. Fourth, Mr. Haynes, with Sir Joseph Paxton, feathered and flamed bizarres; Alice, feathered, and Triomphe Royale, flamed roses; Victoria Regina, feathered, and Talisman, flamed byblœmens. Fifth, Mr. W. Kitchen, Marple, with Storer's Seedling, feathered, and San Josef, flamed bizarres; Modesty, feathered, and Mabel, flamed roses; Trip to Stockport, feathered, and Lord Denman, flamed byblœmens. Sixth, Mr. Moorhouse, with Masterpiece, feathered, and Sir Joseph Paxton, flamed, Mrs. Lea, feathered, and Aglaia, flamed roses; Mrs. Hepworth, feathered, and Bessie, flamed byblœmens. Seventh, Mr. J. H. Wood, Middleton, with Sir Joseph Paxton, feathered, and Wm. Lea, flamed bizarres; Heroine, feathered, and Mabel, flamed roses; Alice Grey, feathered, and Talisman, flamed byblœmens. Eighth, Mr. W. Dymock, Stockport, with Lord R. Churehill, feathered, and Dr. Hardy, flamed bizarres; Seedling, feathered, and Annie M'Gregor, flamed roses; King of the Universe, feathered, and Seedling, flamed byblœmens.

Class 3. *Six dissimilar Tulips, one feathered and one flamed of each class, for small growers only.*—First, Mr. W. Preseott, Bedford Leigh, with Sir Joseph Paxton, flamed, and Lord Lilford, feathered bizarres; Miss Edwards,

feathered, and Annie McGregor, flamed roses; Mrs. Pickerill, feathered, and Adonis, flamed byblœmens. Second, Mr. John Morris, Bedford Leigh, with Sir Joseph Paxton, feathered and flamed bizarres; Industry, feathered, and Mdme. St Arnaud, flamed roses, Violet Amiable, feathered, and Lord Denman, flamed byblœmens. Third, Mr. A. Collinge, Middleton, with Sir Joseph Paxton, feathered and flamed bizarres; Modesty, feathered, and Aglaia flamed roses, Alice Grey, feathered, and Duchess of Sutherland, flamed byblœmens.

Class 4. *Three feathered Tulips*.—First, Rev. F. D. Horner, with Masterpiece, Modesty, and Mrs. Cooper; second, Mr. Prescott, with Lord Lilford, Modesty, and Bessie; third, Mr. Needham, with Wm. Annibal, Modesty, and Elizabeth Pegg; fourth, Mr. Bentley, with Masterpiece, Comte de Vergennes, and William Bentley; fifth, Mr. Morris, with John Ratcliffe, Modesty, and Bessie; sixth, Mr. Moorhouse, with Masterpiece, Modesty, and Trip to Stockport.

Class 5. *Three flamed Tulips*.—First, Rev. F. D. Horner, with Samuel Barlow, Mabel, and an unknown variety; second, Mr. Needham, with Sir Joseph Paxton, Mabel, and Talisman; third, Mr. Bentley, with Dr. Hardy, Mabel, and Mrs. Ramsbottom; fourth, Mr. Morris, with Sir Joseph Paxton, Mabel, and Lord Denman; fifth, Mr. Prescott, with Sir Joseph Paxton, Annie McGregor, and Lord Denman; sixth, Mr. Haynes, with Sir Joseph Paxton, Mabel, and Adonis.

Class 6. *Pair of Tulips, one feathered and one flamed, for maiden growers*.—First, Mr. G. Edom, Epsom, Surrey, with Sir Joseph Paxton and Mrs. Lea; second, Mr. Collinge, with Sir Joseph Paxton and Alice Grey.

Class 7. *Pair of Tulips, one feathered and one flamed*.—First (Samuel Barlow Memorial Prize), Mr. Prescott, with Sir Joseph Paxton and Annie McGregor; second, Mr. Needham, with Sir Joseph Paxton and Masterpiece; third, Rev. F. D. Horner, with Sir Joseph Paxton and Miss Edwards; fourth, Mr. Bentley, with Sir Joseph Paxton and Masterpiece; fifth, Mr. Haynes, with Sir Joseph Paxton and George Hayward; sixth, Mr. Moorhouse, with Sir Joseph Paxton and Masterpiece.

Class 8. *Single Blooms*.—

Feathered Bizarres.

- 1 Mr. Moorhouse, with Masterpiece
- 2 Mr. Bentley, with Lord F. Cavendish
- 3 Mr. Needham, with Storer's 106
- 4 Mr. Prescott, with Lord Lilford
- 5 Mr. Bentley, with General Grant
- 6 Mr. Haynes, with Ajax
- 7 Mr. Morris, with Sulphur
- 8 Mr. Bentley, with Duke of Devonshire
- 9 Mr. Bentley, with Lord Stanley
- 10 Mr. Bentley, with Sir Jos. Paxton

Feathered Byblœmens.

- 1 Mr. Kitchen, with Trip to Stockport
- 2 Mr. Needham, with King of the Universe
- 3 Mr. Needham, with Elizabeth Pegg
- 4 Mr. Kitchen, with Violet Amiable
- 5 Mr. Needham, with Queen of the May
- 6 Mr. Moorhouse, with Trip to Stockport
- 7 Mr. Needham, with Adonis
- 8 Mr. Needham, with Bessie
- 9 Mr. Needham, with Mrs. Jackson
- 10 Mr. Bentley, with Lord Melbourne

Flamed Roses.

- 1 Mr. Kitchen, with Mabel
- 2 Mr. Prescott, with Annie McGregor
- 3 Rev. F. D. Horner, with Mabel
- 4 Mr. Needham, with Queen of England
- 5 Mr. Kitchen, with Clío
- 6 Rev. F. D. Horner, with Industry
- 7 Mr. Needham, with Kate Connor
- 8 Mr. Kitchen, with Rose Hill
- 9 Mr. Wood, with Aglaia
- 10 Mr. Kitchen, with Rose Celestial

Class 9. *The best feathered Tulip in the whole exhibition*.—Mr. Needham, with William Annibal. *The best flamed Tulip in the whole exhibition*.—Rev. F. D. Horner, with Sir Joseph Paxton.

Class 10. *Six dissimilar breeder Tulips, two of each class*.—First, Rev. F. D. Horner, with Mrs. Barlow and Rosy Morn, roses; Dulcie and Fairy Ring, byblœmens; Red Rover and Sir Joseph Paxton, bizarres. Second, Mr. Bentley, with Mrs. Barlow and Rose Hill, roses; Beauty of Litchurch and Bridesmaid, byblœmens; Goldfinder and Sir Jos. Paxton, bizarres. Third, Mr. Needham, with Mrs. Barlow and Rose Hill, roses; Bridesmaid and Adonis, byblœmens; Goldfinder and Sir Jos. Paxton, bizarres. Fourth, Mr. Moorhouse, with Mrs. Barlow and Mabel, roses; Bridesmaid and Agnes, byblœmens; Sir Jos. Paxton and Dr. Dalton, bizarres. Fifth, Mr. Kitchen, with Rose Hill and Mrs. Barlow, roses; Alice Grey and Martin's 117, byblœmens; Sir Joseph Paxton and Goldfinder, bizarres. Sixth, Mr. W. Mellor, Wakefield, with Mabel and A. McGregor, roses; George Hardwick and Sarah, byblœmens; W. Wilson and Hardwick's Seedling, bizarres.

Class 11. *Three breeder Tulips, one of each class*.—First, Rev. F. D. Horner, with Mrs. Barlow, Fairy Ring, and Sir J. Paxton; second, Mr. Bentley, with Rose Hill, Queen of the May, and Lloyd's 47; third, Mr. Needham, with A. McGregor, Glory of Stakehill, and Goldfinder; fourth,

Mr. Prescott, with Mr. Barlow, Adonis, and Wm. Wilson; fifth, Mr. Moorhouse, with A. McGregor, Bridesmaid, and Sir J. Paxton; sixth, Mr. Kitchen, with Mabel, Martin's 117, and Sir J. Paxton; seventh, Mr. Mellor, with A. McGregor, Adonis, and Sulphur; eighth, Mr. Morris, with Mrs. Collier, Adonis, and Sulphur.

Class 12. *Single Blooms*.—

Bizarre Breeders.

- 1 Rev. F. D. Horner, with Sir J. Paxton
- 2 Mr. Bentley, with Goldfinder
- 3 Rev. F. D. Horner, with Wm. Lea
- 4 Mr. Bentley, with Sir J. Paxton
- 5 Rev. F. D. Horner, with Seedling
- 6 Rev. F. D. Horner, with Seedling
- 7 Mr. Bentley, with Richard Yates
- 8 Mr. Needham, with Lloyd's Seedling

Rose Breeders.

- 1 Rev. F. D. Horner, with Lady Grosvenor
- 2 Rev. F. D. Horner, with Rosy Morn
- 3 Mr. Moorhouse, with Mabel
- 4 Rev. F. D. Horner, with Mrs. Barlow
- 5 Mr. Bentley, with A. McGregor
- 6 Rev. F. D. Horner, with Lady Grosvenor
- 7 Rev. F. D. Horner, with Aurora
- 8 Rev. F. D. Horner, with Seedling No. 8

Byblœmen Breeders.

- 1 Mr. Bentley, with Agnes
- 2 Rev. F. D. Horner, with Fairy
- 3 Rev. F. D. Horner, with Fairy Ring
- 4 Mr. Bentley, with Adonis
- 5 Rev. F. D. Horner, with Seedling
- 6 Mr. Needham, with Talisman
- 7 Mr. Bentley, with Leach's Seedling
- 8 Mr. Needham, with Bridesmaid

The best breeder in the show was Mr. Horner's seedling byblœmen Fairy Ring.

BUTLEY TULIP SOCIETY.

THE seventy-second annual exhibition was held at Butley, near Macclesfield, on Friday, May 28th. Owing to the unfavourable nature of the season there were not as many exhibitors as usual, Messrs. Wood, Prescott, and Morris not putting in an appearance. The quality of the flowers left little to be desired, and it was generally conceded that it was the best show for many years. The great prize at Butley is a silver cup for the best stand of six rectified flowers, one feathered and one flamed of each class. It was worthily won by Mr. J. W. Bentley of Stakehill, with an excellent stand, comprising Sir Joseph Paxton, flamed, and John Mills, feathered bizarres; Chancellor, flamed, and King of the Universe, feathered byblœmens; Mabel flamed, and Julia Farnese, feathered roses. Mr. C. W. Needham was a good second, and Mr. Kitchen third. The Judges, Messrs H. Housley (Stockport) and R. Chadwick (Butley), also made the following awards.

Feathered Bizarres.

- 1 Mr. Needham, with Wm. Annibal
- 2 Mr. Needham, with Wm. Annibal
- 3 Mr. Bentley, with Masterpiece
- 4 Mr. Kitchen, with Sulphur
- 5 Mr. Bentley, with Lord F. Cavendish
- 6 Mr. Kitchen, with Paul Pry
- 7 Mr. Bentley, with Garibaldi
- 8 Mr. Bentley, with Luke Ashmole
- 9 Mr. Needham, with Magnum Bonum

Feathered Roses.

- 1 Mr. Bentley, with Modesty
- 2 Mr. Needham, with Modesty
- 3 Mr. Bentley, with Julia Farnese
- 4 Mr. Bentley, with Mabel
- 5 Mr. Bentley, with Alice
- 6 Mr. Kitchen, with Heroine
- 7 Mr. Dymock, with Seedling
- 8 Mr. Bentley, with Mrs. Wood
- 9 Mr. Needham, with Mrs. Collier

Feathered Byblœmens.

- 1 Mr. Bentley, with Bessie
- 2 Mr. Needham, with King of the Universe
- 3 Mr. Needham, with Elizabeth Pegg
- 4 Mr. Bentley, with Camp's Seedling
- 5 Mr. Kitchen, with Trip to Stockport
- 6 Mr. Needham, with Queen of the May
- 7 Mr. Bentley, with Bessie
- 8 Mr. Needham, with Wm. Parkinson
- 9 Mr. Jones, with Bertha

Flamed Bizarres.

- 1 Mr. Needham, with Sir J. Paxton
- 2 Mr. Kitchen, with San Josef
- 3 Mr. Bentley, with Samuel Barlow
- 4 Mr. Needham, with Dr. Hardy
- 5 Mr. Bentley, with Sulphur
- 6 Mr. Needham, with Hepworth's Seedling
- 7 Mr. Needham, with Sir J. Paxton
- 8 Mr. Needham, with J. Booth
- 9 Mr. Bentley, with Lord Stanley

Flamed Roses.

- 1 Mr. Kitchen, with A. McGregor
- 2 Mr. Needham, with Aglaia
- 3 Mr. Bentley, with A. McGregor
- 4 Mr. Bentley, with Madame St. Arnaud
- 5 Mr. Bentley, with Mabel
- 6 Mr. Needham, with Triomphe Royale
- 7 Mr. Bentley, with Sarah Headly
- 8 Mr. Needham, with Kate Connor
- 9 Mr. Kitchen, with Rose Hill

Flamed Byblœmens.

- 1 Mr. Needham, with Talisman
- 2 Mr. Bentley, with Mrs. Ramsbottom
- 3 Mr. Needham, with Hepworth's Seedling
- 4 Mr. Bentley, with Talisman
- 5 Mr. Kitchen, with Duchess of Sutherland
- 6 Mr. Bentley, with Black Diamond
- 7 Mr. Dymock, with Seedling
- 8 Mr. Kitchen, with Lord Denman
- 9 Mr. Bentley, with Chancellor

Three breeders, one of each class.—First, Mr. Bentley, with Lloyd's 47, Rose Hill, and Alice Grey; second, Mr. Kitchen, with Sir J. Paxton, Rose Hill, and Alice Grey; third, Mr. Hague, with Dr. Hardy, Industry, and Alice Grey.

Bizarre Breeders.

- 1 Mr. Bentley, with Lloyd's 47
- 2 Mr. Bentley, with Goldfinder
- 3 Mr. Bentley, with Sir J. Paxton
- 4 Mr. Bentley, with Excelsior
- 5 Mr. Needham, with S. Barlow

Rose Breeders.

- 1 Mr. Bentley, with A. McGregor
- 2 Mr. Needham, with Mrs. Barlow
- 3 Mr. Bentley, with Queen of England
- 4 Mr. Kitchen, with Rose Hill
- 5 Mr. Needham, with Lloyd's 220

Byblæmen Breeders.

- 1 Mr. Needham, with Bridesmaid
- 2 Mr. Bentley, with Beauty of Litchurch
- 3 Mr. Bentley, with Alice Grey
- 4 Mr. Bentley, with Adonis
- 5 Mr. Kitchen, with Unnamed.

Best yellow self, Mr. Needham, with Citronella. Best white self, Mr. Bentley, with Cygnet.

The extra prizes for the best feathered, the best flamed, and the best breeder Tulips in the show were all won by Mr. Bentley, with Sir J. Paxton, flamed; John Mills, feathered; and Lloyd's 47, breeder. After the judging the members and friends dined together, Mr. C. W. Needham, the President for the year, occupying the chair.

TAMWORTH PANSY AND VIOLA SHOW.

DESPITE the unpropitious weather that had predominated for the last few weeks, this important exhibition, which was held on the 26th ult., in a large marquee at Bolehall House, the charming residence and grounds of Mr. Wm. Sydenham, the well-known cultivator and raiser of Violas and Fancy Pansies. The recent show was, in some respects, not so good as usual, the entries also, from the same cause, being less; otherwise it proved successful, and was well attended by visitors.

The leading feature of the show was Mr. W. Sydenham's extensive and much varied display of Pansies and Violas, and for which the gold medal was worthily awarded. Another attractive feature by the same gentleman was a beautiful Jubilee design of Violas forming the initials V.R., the upright stands having been made for the purpose out of Sydenham's rustic table adornments. In the centre the "V" was composed of the rich crimson purple Councillor W. Waters, and the "R" in the rayless deep yellow Pembroke, evidently the best yellow self in cultivation, as seen at the present time in the Sydenham collection. The variety in question was awarded a F.C.C. at Regent's Park Show last year, and has "come to stay" evidently. The flank designs, representing the years 1837 and 1897, were worked in white and yellow and blue and white respectively, the varieties employed being Niphetos and Stephen for the former, and Niphetos and Mrs. H. Bellamy for the latter. Altogether it was an appropriate, well conceived arrangement, reflecting much credit on the decorators, Mr. Sydenham's two daughters. In addition to the foregoing there were also other similar designs by the same artists, one being a most effective Prince of Wales' Plumes, composed of the white Niphetos and Formidable, a new seedling, catalogued 1897, a lovely variety, colour soft lavender self, with white and yellow centre. Flanking this were two representations of Fir trees, which were respectively decorated with Dr. Sculthorpe, a pale creamy self, rayless, a real acquisition, and Amy Barr, a dark pink with deeply veined white centre, a charming variety. The whole of the designs were more or less supplemented with a fringement of Fern fronds and Asparagus sprays judiciously introduced.

In the competitive classes Mr. J. M. Johnston was awarded the first prize for a very handsome cross, composed of white and purple Violas and Maidenhair Fern; the second prize being secured by Mr. R. Pemberton with a smaller, but very pretty arrangement. Two charming exhibits were seen in the class open for any design, in which any kind of flowers and foliage were allowed, the first prize falling to Mr. J. M. Johnston with a lyre design, the framework being composed of white and light blue Violas, with a centre of white, lilac, and blue Forget-me-not. Mrs. Lovatt obtained the second prize with also an effective design representing a harp. A certificate of merit was awarded to Mr. R. Sydenham, Birmingham, for a charming display of Carnations and Roses, and Mrs. Chadwick, Hints Hall, lent a quantity of ornamental foliage and flowering plants, which added much to the exhibition. The attention of specialists was drawn to a new seedling Viola named A. Sydenham, an entirely new character, the curious feature being that every petal was crimped all over.

In the cut bloom classes, open, including trade growers, for forty-eight Fancy Pansies, dissimilar, the first prize and gold medal was awarded to Mr. A. Lister (Rothsay) with a meritorious stand, including several novelties, the second prize falling to Mr. J. Smellie for a worthy assortment. In the three subsequent classes—viz., for twenty-four blooms, twelve blooms, and six seedlings, the awards fall as in the order named; whilst for the best exhibit of Violas, artistically shown, Mr. Smellie secured the chief honours with a collection arranged with much taste.

There was a fairly strong show in the "open amateurs' division," and in a few instances the competition was keen. The exhibits most distinguished were those shown by Mr. T. Nadin (Derby), Mrs. R. Lovatt (Newport), Mr. J. M. Johnston, and Mr. J. W. Paul.

The local amateurs' class formed a somewhat small but interesting show. Mr. J. W. Paul (Wilnecote) secured first honours in the classes for twelve and six Pansies (Fancy) respectively, and Mr. Johnston secured the first award in the Viola class. There was little competition in the local cottagers' section, and the first and second prizes fell to Messrs. R. Hatwell (Frasley) and H. Machin (Tamworth).

Mention was nearly omitted of the competition in the class for twelve Show Pansies, dissimilar, not a strongly represented class, the first and second prizes being awarded to Messrs. A. Lister and J. Smellie respectively for stands of very good blooms.

The band of the Bedfordshire Regiment was in attendance, and the visitors availed themselves of the permission to inspect the splendid array of Pansies and Violas in Mr. Sydenham's nursery department.

During the course of a brief inspection amongst the forthcoming novelties growing in the various quarters the writer's attention was drawn to a few possessing considerable merits, and conspicuous amongst the Violas was one named Charles Hughes, a decided improvement on Peter Barr, and with a broader border of a deeper blue than the older beautiful variety. A veritable gem is a new one of the Violetta type, called "Robin," of very dwarf habit, and producing a mass of bloom throughout the season, colour pale blush. Another striking Viola is "Devonshire Cream," an appropriate name. It is a seedling from President, and much more floriferous, and evidently destined to supplant such as the famous Sylvia. As a strong opponent of such as Archie Grant and True Blue, one named Britannia, a seedling from Blue Gown, but very much darker, with an excellent habit, claimed special attention.

Amongst Fancy Pansies one called Felicia, a fine thing with purple blotch edged with maroon, was noticeable, whilst Turquoise, with a beautiful circular dark purple blotch on an orange ground, is destined to become very popular. Exceedingly attractive is Mrs. R. G. Moir, with its large circular velvety dark blotches, laced pure white, tinted with crimson, upper petals white, with a broad band of reddish purple, picoteed with white. Amongst the many other acquisitions the noted Tamworth Yellow holds its own, and is one of the best summer flowers extant, as the sun does not readily fade the colour. It is a great favourite with the public.

THE YOUNG GARDENERS' DOMAIN.

EUCHARIS AMAZONICA.

THE Eucharis is a plant of great beauty in both foliage and flowers, and should take front rank amongst stove flowering plants. It is of easy culture when once its requirements are understood. When healthy the plants do not like being interfered with at the roots. Unhealthy plants should be taken out and thoroughly cleaned. Large plants may be divided to increase the stock, or given larger pots as needed. A compost of three parts rough turfy loam to one part each of dry Oak leaves passed through an inch sieve, charcoal, and sand, and to every bushel of compost a 6-inch pot of half-inch bones we find suitable.

See that the pots are well drained, as the plants like an abundance of water when growing, but it should pass quickly away. Pot firmly, and place them in a temperature of 70° at night, with a corresponding rise in the day. Shade and syringe them two or three times a day, according to the weather. Watering must be carefully attended to. Some growers partly dry the plants off and keep them cool, but it is the safest plan to keep them fairly moist all the year round with a fall of 5° to 10° in temperature when not in active growth.

Mealy bug and the Eucharis mite are the two most troublesome pests; the former may be kept down by frequent spongings. The mite seldom attacks healthy plants, but should it do so wash the bulbs in some approved insecticide. When well rooted the plants should receive liberal supplies of liquid manure two or three times a week. If the above details of culture be carried out, healthy plants should flower two, and sometimes three times a year.—GROWER.

PACKING.

IN most private gardens, as well as the market nursery, packing is a necessity, but the private gardener does not always do his packing the same as the market grower.

GRAPES.—There are two or three different methods of packing Grapes; one of them is in deep square boxes made for the purpose. The box is well lined with wood wool, both at the bottom and sides. A sheet of tissue paper is put over this, and the Grapes packed in as close as possible with the bunches upright, the bottom of each bunch at the bottom of the box. Over the top of them is put tissue paper, then wood wool, and the lid is fastened securely.

Another method, and the one chiefly in use by market growers, is packing in baskets. The baskets have plenty of wood wool at the bottom, covered over with tissue paper. The bunches are laid on this as closely as possible, and the baskets covered with strong paper, taking care that this paper does not touch the Grapes, or the bloom would be rubbed off.

Exhibitors when sending Grapes to shows usually fix the bunches on the show-boards previous to starting, fastening them down with string. The boards are then placed in a box made to hold them firmly, or so that the board cannot move about. A handle is fixed on the top, or two at the sides, and the box labelled "This side up, with care."

MELONS.—If Melons are to be sent away singly, a small Grape box is suitable for the purpose, the bottom of the box lined with wood wool. The Melon is wrapped with tissue paper, and then placed in the centre of the box, sides and top being then well filled with the wool, and the lid nailed on. If Melons are to be sent away in large quantities, a box 4 feet long, 3 feet wide, and about 1 foot deep will hold from a dozen to fifteen fruits, according to size. The box is well covered at the bottom with wood wool or hay, each fruit being wrapped in tissue paper. Great care is taken that they do not touch each other, and the spaces between are filled with wood wool as the Melons are placed in the box. A good layer of wool is put over the top, taking care not to break the short piece of stalk that is cut with each fruit.

PEACHES AND NECTARINES.—These, like Melons, travel the best a single layer. Boxes about 4 inches deep, made to hold about eighteen or twenty-four fruits, are the most suitable size; a layer of cotton wool at the bottom, and over it a sheet of tissue paper. The Peaches are

also wrapped in tissue paper, and then placed in the box, leaving a small space between them, to be filled with bran or clean sawdust. Another layer of cotton wool is placed on the top previous to applying the lid.

Another way is to wrap tissue paper round the bottom half of the fruit, and cotton wool, cut into strips, round the paper. As this is done they are placed close to each other in a box in which cotton wool has previously been laid. A sheet of tissue paper is then placed over them, and another layer of wool on the top. Inferior Peaches and Nectarines for culinary purposes may be packed in any ordinary square box lined with paper and the bottom covered with bran or cotton wool. A layer of fruit is placed on this and covered well over with half an inch of bran, a slight shake given to the box causing the bran to fill all crevices between the fruit. Other layers of bran and fruit follow until the box is full.

STRAWBERRIES.—These for dessert must be picked when dry, each fruit with a stalk about half an inch long. Strawberry boxes about 2 inches deep hold one layer. A sheet of tissue paper is spread in the box. Their own leaves are the best to pack them in, using one leaf for each fruit. It should be laid in the leaf with the end of the fruit towards the apex and a twist given to the leaf round the stalk of the fruit. The leaf will cover three parts of the Strawberry. The fruits are placed in the box as each is wrapped up, and as close together as possible. In this manner the upper part of the fruit is uncovered, and over this is spread soft leaves until the box is full. This method is chiefly practised in private gardens. Market growers usually pack their Strawberries in punnets, one or more layers of fruit in each, and boxes or baskets are made to hold a certain number of punnets. For preserving, Strawberries are gathered without stalks, and an ordinary box, lined with Cabbage or Rhubarb leaves, answers for packing them. All kinds of fruit for preserving may be packed in the same way.—ELVEDEN.

TOMATO CULTURE.

THOUGH the Tomato was introduced just before the Potato it is only in recent years it has become so popular with all classes and so largely cultivated. Although much has naturally been written about Tomatoes I may be excused for describing practice that has given satisfactory results; still, whether in growing for market, exhibition, or home consumption we should always try to improve on the past, no matter how excellent the results may have been. This is the spirit which should animate all young gardeners in doing the work entrusted to them.

CULTIVATION.—Our first seed is sown about the middle of December, and the pots placed in a hothed till the plants appear, when they are removed to a shelf near the glass in an early vinery where the temperature is seldom under 60°. We sow thinly in well-drained pots and pans, and use equal parts of loam and leaf mould. The next sowing is made in January and February for growing under glass; the third in March for planting outside—strong plants in 6-inch pots with some fruit set by the end of May. Plants are raised early in July for fruiting during the winter, the crop being set before the dark days come.

The plants, when they have two rough leaves, are potted singly in 3 and 5-inch pots and plunged in a hotbed, the house having a temperature of about 60°. Those in 5-inch pots are transferred when nicely rooted to the fruiting pots and boxes, not waiting till the plants are root-bound. Those in 3-inch pots are transferred when ready to the 6-inch size. The compost used for potting from the seedling stage till the final shift is composed of three parts loam and one part of equal shares of leaf mould and horse droppings, with a dusting of bonemeal. The soil is warmed for the early plants before using, and they are not taken to a cool place to be potted, a practice by which many get chilled. The soil used for the final shift is the top spit from a deer park, cut about 3 inches deep and left till the grass is decayed before using. Room is left for top-dressing several times, "light and often" being my maxim in this work.

Boxes are preferred to pots, the size chiefly employed being 30 inches long, 20 deep, and 13 wide, each holding three plants. Copious supplies of liquid manure are given when the roots have taken firm possession of the soil. Soot, cow, sheep, and pigeon manure are used, varying them each week. Occasionally sprinkling the surface of the soil with guano, and a mixture given some time ago in the Journal, of bone superphosphate eight parts, nitrate of soda four parts, and muriate of potash two parts, watering in when used, acted beneficially.

All the plants are grown on the single stem system, as after trials it was found the heaviest weight of fruit was thus obtained from a given space. All side growths are rubbed out as they show, as if left to extend they rob the plants and fruit. Seldom are any leaves or part of leaves cut off, as they are required if the plants are carrying a heavy crop of fruit in various stages of ripening. Some of the finest fruit (20 ozs. in weight), and heaviest crops I ever grew were cut from pots plunged in a bed of leaves nearly cool, into which the roots spread over 15 feet from the pots. The growth was strong, and the leaves very large. The tiers of fruit when colouring touched one another, and were compared to hanks of Onions. Perfection and Frogmore Selected were the varieties thus grown, and only a few half leaves were cut off over the fruit.—W. T., Ireland.

HARDY FRUIT GARDEN.

Syringing and Cleansing Wall Trees.—The liability of the shoots of many wall trees to be attacked with insects, chiefly aphides, at this season necessitates effective measures being taken to extirpate them. Cherries, Plums, Peaches, Nectarines, Apricots, Gooseberries, and Currants are the most frequently attacked. The causes of the annual insect invasion are due to impoverishment of the roots by poor or dry soil, and unsuitable positions. A few insects once established on the young shoots soon multiply rapidly, until quite a colony is formed on the youngest leaves and succulent parts. If the infested shoots are not too numerous the insects may be destroyed by the process of dipping the ends of the shoots in a portable vessel containing some effective solution. Softsoap dissolved at the rate of 2 ozs. to the gallon of water is a very common and useful insecticide, which may be made more potent by adding 1 pint of tobacco water. This mixture will do either for dipping shoots or for a general syringing of the trees, operating in the evening when the sun is declining.

The numerous advertised insecticides are also good, and frequently more convenient to prepare for immediate use. Isolated shoots only lightly infested with aphides may be dusted with tobacco powder. Shortly afterwards wash it off again along with the destroyed insects by a vigorous syringing from a hand syringe or garden engine.

As a means, too, of maintaining the trees regularly clean and preventing the establishment of insects frequent syringing with clean water in warm weather is indispensable. Root moisture must be kept up according to the weather and demands of the trees. This is an important precaution against ill health. Some trees may be slightly affected with mildew, a remedy for which is sulphide of potassium, half ounce to a gallon of water.

Training and Treatment of Young Fruit Trees.—Regular attention in training-in the young shoots of recently planted wall trees is a most important point in laying a foundation of branches, and properly filling in the space available. As far as possible the branches should be developed equally. This may be accomplished by judiciously suppressing the strong shoots and encouraging the weaker. If not desirable to shorten or reduce the length of any rampant leaders depress them and elevate the weaker to more upright growth. In laying in the shoots for furnishing allow each abundant room. Fan-trained trees may have all the wood possible laid in on these lines. The principals should be trained far enough apart to admit secondary branches and lateral shoots. Wood of medium strength is in most cases to be preferred to strong sappy growths. Maintain the foliage clean and healthy by syringing in warm weather.

Trees trained in restricted forms for the most part require extension of the branches already originated, with possibly some additional in suitable positions. The leaders of each branch ought to extend unchecked, but the side shoots advancing into long growths must be summer pruned. Fruit spurs will then have a chance of forming at their base. Shoots, however, forming spur growths in a natural manner should obviously be left alone.

Apply water at intervals to the roots of trees where the ground dries quickly and the roots are liable to suffer. With young trees repeated heavy waterings ought to be avoided. It is more desirable to mulch the surface with littery manure after a copious application. This arrests evaporation, and the trees benefit from the more regular moisture in the soil accordingly.

Established Wall Trees.—*Laying in Wood.*—The reserved shoots of Peaches, Nectarines, Apricots, Plums, and Cherries must be selected and carefully laid in along the desired direction they are intended to be trained. It is not necessary that they be permanently secured to the wall or trellis at present, but they ought to be retained in position. They can temporarily be fixed by the aid of pliable young shoots cut in suitable lengths. Lay them across the growths desired to be secured, fixing the ends underneath the strong branches. Superfluous shoots must be dealt with by shortening or cutting out.

Outdoor Vines.—Tying and stopping the side shoots of Vines on walls or trellises demands now frequent attention. Disbudding having been effectively carried out, there should remain on each spur not more than two shoots. One of these ought to be showing a bunch of fruit. The other may probably do so too, but it is not necessary that both carry a bunch. If the shoot nearest the main rod bears the bunch and is retained the other may be dispensed with. Should, however, the contrary be the case, both shoots may be preserved, the lower one affording prominent buds for pruning to in winter. Stop the fruiting shoots one or two leaves beyond the bunch, according as room is available. Shoots retained, but which are not showing fruit, stop at the seventh leaf. Those required to extend into long canes for filling vacancies do not stop until they have attained a length of 3 or 4 feet. A fresh leader may then be allowed to grow unchecked. The ripest portion of such canes, and which will be fruitful the following year, will be that below the stopping point this season. The principal leaves must be carefully preserved, but the lateral growths issuing from their axils may be broken out.

FRUIT FORCING.

Peaches and Nectarines.—Earliest House.—When the fruit is all gathered from individual trees, the wood on which it has been produced should be cut away to the shoot at its base, which is to afford the bearing wood for next season, except if the fruit has been produced on wood that is necessary to retain for the extension of the trees. All growths not absolutely necessary for bearing next season, or for the extension of the trees, must be cut away, as it is important the foliage be fully exposed to light and air, and it is equally essential that it die naturally, not prematurely through attacks of red spider or lack of moisture at the roots. Employ the syringe freely, keep the inside border well watered, and the outside border must not be neglected if the weather be dry. Admit all the air possible, and when the buds plump, and the wood thoroughly ripened, the roof lights, where moveable, may be taken off.

Trees Ripening their Fruit.—Ventilate freely, leaving a little air on constantly, and to insure the preservation of the foliage in health sprinkle the paths and borders with water in the morning and afternoon, not allowing the soil to become dry, but giving water as required. A mulching of short spent material is very useful in preventing the surface cracking, and the roots going down in quest of moisture. Syringing must cease directly the fruit commences to soften for ripening, or the moisture will cause the skin to crack and leave an unpleasant musty flavour, as well as spoiling its appearance.

Trees of Midseason Varieties Started in January.—After the fruit takes the last swelling give every attention to the trees in watering with liquid manure, or affording water through a mulch of short manure. The shoots may be allowed to extend, not pinching the laterals in too closely, but they must be prevented shading the fruit, raising this with its apex to the light. To secure this place laths across the trellis, securing them to the wires. Continue forcible syringings morning and afternoon until the fruit begins ripening, then cease syringing, but do not allow the border and other surfaces to become parchingly dry, as moderate moisture, provided the ventilation is liberal, will not injure the fruit, and it is absolutely necessary for the benefit of the foliage.

Trees Started in February.—The fruit of these is stoning. It has made satisfactory progress, attaining to a good size, as is always the case when the trees are not hurried, nor overcropped, and well attended to as regards nourishment and proper exposure of the foliage to light and air, with free ventilation on all favourable occasions. To continue the fruit in steady progress and insure its stoning satisfactorily there must be no deficiency of moisture at the roots, and the foliage must be kept clean by daily syringings, also, if necessary, by the prompt application of an insecticide. Continue the temperature at 60° to 65° artificially, and allow a free circulation of air between 70° and 75°, having it full when the latter is reached, and close at 75° with plenty of atmospheric moisture. If the temperature rise to 80° or 85° it will not do any harm, but admit a little air before nightfall, so as to allow the pent-up moisture to escape and the temperature to gradually cool through the night. Commence increasing the ventilation with the advancing heat from 65°.

Later Houses.—If desired to retard the fruit in any of these, so as to prolong the season of supply, it is best effected by freer and lengthened ventilation during the day and night when mild. Indeed there is only need to ventilate day and night to keep the crop back so as to ripen about the same time, as that usually occurs with trees against walls, and by judicious ventilation the fruit may be had over a lengthened period.

Vines.—Early House.—As soon as the Grapes are cleared give the inside borders a thorough supply of liquid manure, or a top-dressing of fertilisers washed in moderately. Keep the ventilators open constantly even in cold weather. Syringe thoroughly to cleanse the foliage, and repeat occasionally to keep the old leaves healthy. Fresh laterals will soon be produced, and cultivators should maintain an even growth all over the Vines, pinching the gross laterals, and encouraging the weak. The mulching or covering having been removed from the outside border, with just enough of the lighter part left to protect the roots, a good watering with liquid manure may be given, but this will only be needed where no rain has fallen. Avoid heavy mulching.

Second Early House.—Vines started at the new year have the Grapes ripening, but there is fully a fortnight to three weeks difference in the time of ripening between Vines carrying light crops and those with heavy burdens. Maintain a circulation of warm rather dry air constantly, increasing the ventilation early. Keep the floors well damped on hot days, with a view to check excessive evaporation, allowing the temperature to fall to 60° at night when cold, or 65° when warm, with sufficient warmth in the pipes to prevent water condensing. If there is likely to be any want of finish allow the Vines time by giving as long a rest at night as possible. If there is any doubt about the roots lacking moisture examine the border, and if found necessary give a thorough soaking in the morning of a fine day, and when soaked in mulch with a little light material. Moderate moisture is essential to the health of the foliage, hence damping the floors must be resorted to occasionally, as there is no fear of its damaging ripe Grapes at this season if only it be accompanied with air; besides, the moisture will assist in keeping the Grapes, and to prevent colour being taken out of Hamburgs a double thickness of herring net should be drawn over the roof lights. Allow a moderate extension of the laterals to encourage root action.

Midseason Houses.—Vines in these will be in various stages of development, according to the time of starting. Those which have stoned will be swelling the berries fast, and the borders should have a soaking of

tepid water through a mulching an inch or two thick. The drainage being good, water will be needed once a week if the border is limited to a small area, or fortnightly intervals, until the Grapes are somewhat advanced in colouring, when it must be stopped. Admit a little air constantly at the apex, and ventilate freely in the early part of the day, closing early with sun heat and a genial condition of the atmosphere. Fire heat will only be necessary to secure 60° to 65° at night, and 70° to 75° by day, keeping through the day at 80° to 85°, and closing sufficiently early to run up to 90° or 95°. This will insure the berries swelling to a good size, and with a free circulation of air a good finish may be secured.

Grapes Stoning.—During this process the Vines should have a regular temperature of about 65° at night, and 70° to 75° from artificial heat, if the Grapes are wanted by a given time, but if not 65° only need be maintained on dull, cold days; but admit air in good time, always a little at 70° or before after a spell of dull weather, so that any moisture shall be dissipated before the sun acts powerfully upon the foliage. Allow a moderate extension of the laterals, but avoid overcrowding, and supply liquid manure or water, washing in a top-dressing of approved fertiliser, or passing through a mulch of short stable manure. Avoid, however, feeding luxuriant Vines too liberally, especially with ammoniacal or nitrogenous manures, giving in their case dissolved bones, with a little sulphate of potash. This will enable the Vines to maintain steady progress, whilst storing food for the coming season's bearing.

Grapes Scalding.—Muscats and Lady Downe's in the later stages of stoning are liable to scald, therefore must be watched in hot bright weather, and air admitted more freely for a fortnight or three weeks, unless colouring commences, when all danger will be over. Black Hamburgs also are sometimes scorched when the berries are exposed to the direct rays of the sun, which can mostly be avoided by a good spread of foliage, and remedied by a bountiful supply of air by day and a little ventilation constantly, with a genial warmth in the hot-water pipes.

Early Muscat House.—The fruit ripening will need a dry condition of the atmosphere as compared with Black Hamburgs, but avoid great aridity, or the foliage will fall a prey to red spider. Muscats must have time to ripen and acquire that rich amber colour so much prized. Do not allow any deficiency of moisture in the borders, for Muscats are gross feeders, but give tepid liquid manure or water through surface mulching. The supply of water to the roots will to some extent compensate for the drier condition of the atmosphere. Provide a circulation of air constantly, preventing the moisture condensing on the berries by sufficient warmth in the pipes to insure a changing atmosphere. Lateral extension is the best safeguard against shanking at this stage, along with a steady temperature. Avoid sudden fluctuations and depressions. Keep the night temperature at 65° to 70°, 80° to 85° by day, with a little sun, and 90° to 95° with it in full force. Ventilate early, and regulate by the sun's increase, and so with its decline, reduce early, securing as long a day of ripening from sun heat as possible. The old leaves of Muscats are liable to be scorched under powerful sun after a period of dull cold weather. In very bright weather draw a single thickness of tanned netting over the roof lights, which, without impeding too much light, will prevent the condensation of moisture.

PLANT HOUSES.

Caladiums.—Plants that it is intended to grow for conservatory or other forms of decoration in intermediate structures should be placed at once into larger pots. After the plants have started rooting freely in the new soil give them more air, so that firm sturdy growths will follow. Full sunshine may also be admitted to these plants. When grown under close, moist, and shady conditions their foliage falls directly the plants are placed in cooler and more airy quarters—in fact, they are practically useless for many forms of decoration.

Achimenes.—More cuttings may be inserted in 5-inch pots; these root quickly if placed in a moist shady position for a week or ten days, or in the propagating frame. The plants from which cuttings have been obtained should then be allowed to grow or to develop their tubers for another year. When once these are again fairly started into growth weak stimulants should be given them, or else they will grow weakly. Plants rooted some time ago and now in pots should be supported by four or five small stakes and one or two pieces of matting.

Poinsettias.—Do not keep plants growing in too close and warm a structure, or else they will draw up weakly and soon become leggy. They should occupy an intermediate temperature, and air should be given liberally when fine, which will result in sturdy growth. Young plants that need repotting ought to be attended to from time to time, and the soil should be pressed firmly into the pots; loose potting is a great mistake and only encourages soft rapid growth. These plants do well in fibry loam, one-seventh of manure and sand.

Euphorbias.—Cuttings of *E. jacquiniifolia* should now be plentiful, and will root freely if they have been prepared by thorough hardening in a cool airy house for the last fortnight. The young shoots should be taken off just where they are emitted from the old stem with a sharp knife, and if inserted in sandy soil and covered with a bell-glass, shaded from the sun, and kept in a close warm house, the majority will root. If the cuttings have been produced in brisk heat and are then inserted nearly every one will fail. Once sufficient young stock has been raised the old plants, if needed, may be cut back and allowed to start from the base.

Asparagus plumosus nanus.—Large or fair sized plants that display a tendency to form crowns may be divided into small pieces.

The plants soon become established and are useful for various decorative purposes. Cuttings of *A. plumosus* and *tenuissimus* root freely. If portions of the stem with a leaf attached are inserted in sandy soil, in small pots, and stood under hand-lights in a warm house, every one will root, and by winter make useful decorative plants in small pots. Where larger plants are needed repot those that have become too large in 4 and 5-inch pots.

Crotons.—Good heads that were taken off some time ago and are well established in 5 and 6-inch pots may be placed into larger before they become unduly crowded with roots; give each plant room to develop itself so that they do not become one-sided. Side shoots may now be taken from stock plants and rooted; these root freely in hand-lights in heat, if shaded from the sun, and will make good plants for many forms of decoration by autumn. Narrow-leaved kinds are very useful in a small state for table decoration, and these may be rooted in quantity, and when placed into 4 or 5-inch pots should be grown on a shelf close to the glass. Plants that it is necessary to retain for stock may, when the cuttings have been removed, be cut close back and allowed to start from the base.

Dracaenas.—Young plants should be repotted as they need more root room. Those plants that it is necessary to grow into a larger size, and which are now in 5 and 6-inch pots, should be placed into larger as soon as they are ready. These plants should be shaded for a few hours during the brightest and hottest part of the day, or else their foliage will colour too lightly.

THE BEE-KEEPER.

THE WEATHER.

TEN days of bright weather have been very beneficial in the apiary, and stocks which are headed by young queens—i.e., queens which were bred during the summer of 1886, are rapidly improving. Many of the more forward colonies are ready for supering. At this season one can almost tell at a glance the stocks that are headed by young fertile queens; the difference is so great when compared with those having old worn-out queens. There are exceptions, it is true, but as a rule queens are at their best the second season. Now is the time to make a note of those which are doing well, with a view to raising the required number of young queens next month.

It has not been ideal bee weather, owing to the fact that the wind has been in a northerly or easterly quarter the whole of the time, a low temperature prevailing at night. The cold cutting winds, I fear, have damaged the Apple blossom which during that period has been expanded. The sun, though, has been very powerful, necessitated shade for strong colonies of bees. Although the show of bloom on the fruit trees has been better than usual, the Hawthorns, on which the bees work freely, are in marked contrast to what they were last year; at this time they were a sheet of bloom, now only a few scanty blossoms are to be seen.

The Horse Chestnuts, however, make up for the deficiency. The honey, though obtained from that source, is of an inferior quality, and will spoil what might otherwise be a good sample for extracting purposes. In many districts Chestnuts are very plentiful, and where such is the case it is useless attempting to obtain a good sample of run honey early in the season. Partly for this reason, and owing to the fact that there is always a better market (in my experience) for run honey than for sections, we only work a few hives for the latter, and already the bees are working freely in the crates of sections that have been given to them.

PREPARING FOR THE HONEY HARVEST.

All will depend on the preparations now being made in connection with the apiary whether the bee-keeper will derive full benefit from his bees. We cannot command fine bright weather just when it is necessary during the honey flow, but let us endeavour to deserve success by using every means in our power to have all our hives overflowing with bees in each locality when the bulk of the honey is to be obtained. How is this to be done? It may be summed up in one word—Management. Therein lies the whole secret of success or failure in bee keeping.

Continue to give extra frames of foundation, or better still, fully drawn out combs as required, placing them next to the outside frame containing brood. The frame next to the division board usually contains stores and pollen, the latter being always placed near the brood nest for convenience of feeding the young bees. If honey is coming in freely a crate of sections may be placed on the strongest stocks, or if run honey is required a crate of shallow frames may be used instead. By this means the bee-keeper is often able to obtain some early honey which would otherwise be stored in the brood nest. Care must be taken that the hive is full to overflowing with bees, otherwise they will not enter supers. But there are always some colonies in an apiary at this season which are

stronger than others, although all may have received the same treatment. Why this should be the case it is difficult to say, but it is probably owing to the queen commencing to lay earlier in the season than others.

Bees will invariably commence working in supers if the brood nest is restricted, but it is not a plan to be recommended. It is, however, an advantage to do so if there are no other means of obtaining a few early sections; the brood nest may afterwards be enlarged in time to obtain full benefit from the late harvest. Hives that are intended for extracting purposes must receive attention. Those which are full of bees and have no more room for extra frames may have a frame or two of hatching brood, and all the adhering young bees removed and given to a weak colony, the empty space being filled with foundation or combs. By this means all will be in good condition to derive full benefit from the honey flow when it comes.—AN ENGLISH BEE-KEEPER.

BEE NOTES FROM DEVON.

THE year here has opened remarkably well. Fruit blossom was very plentiful, which helped the bees wonderfully; with the advent of May nearly all hives were up to swarming point. I placed supers on several of my hives at the latter part of April. Swarms were reported early in May. My first came off on the 15th, leaving a half filled section on the hive. On Thursday the 20th I had several well-filled sections sealed over ready to take off. This is about ten days later than during the Jubilee year, 1887. The heavy rain early in the spring caused the grass to grow very abundantly, and the Clover is wonderfully thick; with a few showers later on we shall be reaping a glorious harvest from this source. Taking a great interest in bee notes from other places in the *Journal of Horticulture*, I thought you would like to know how we were faring in Devon.—AMBROSE GODSLAND.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Carnation Clip (H. A. D).—We have received the clip, which broke very easily on the first (and, as it proved, the last) application. Another tried in the same way did not break under much greater pressure, and you will not be surprised, therefore, that this is preferred.

Insects on Muscat of Alexandria Grapes (W. H. W.).—The Muscat of Alexandria berries are perfectly clean, and evidently have set grandly either by natural or artificial agency, and are a real pleasure to behold. We searched very carefully for the small insect, and were about giving up the scrutiny, when we came across a small white thing, which was only the empty skin of an aphid. There was nothing else, and it is needless to say that vaporisation with XL All essence will, indeed, kill the pest. The precautionary advice, "Muscat and Lady Downe's Grapes should not be vaporised," is very desirable, as both have been seriously injured in foliage in the later stages, it acting on them similarly to scorching. Though you find your "Muscat and Lady Downe's" appreciate the vaporising equally as much as do any other Grapes when insect pests are present, it is well to bear the caution in mind, as we have found great difference in the susceptibility of Vines at different stages of their growth, this being greatest in the varieties named towards the close of the stoning period, and even when ripening.

Deformed Roses (C. S. M.).—The condition of the malformed bloom is not due to insect attacks, but is the result partially of frost and partially of insufficient nutriment. We have often seen similar examples produced by plants or bushes which have not been pruned so closely as is desirable. Give copious supplies of liquid manure to obtain stronger growths, and in pruning remove all weakly shoots, relying on the stronger cut-back towards the end of March for producing blooms.

Tomato Flowers and Young Fruit Diseased (Constant Reader).—We have often seen Tomato plants in a similar predicament to that which you describe as follows:—"Flowers do not fall off freely, and fruit appears to rot. Plants are very strong, and have set what should be about 3 lbs. of fruit to a plant, and have large trusses of bloom, as many as seventy and eighty blooms on one truss. I ventilate freely, top and bottom by day and top by night, and have genial warmth in pipes day and night." The blossoms enclosed in the letter were dried and crushed in passing through the post, the corolla in some cases adhering to the calyxes, while in other instances the young fruit was quite black. On examining the latter there was seen to be outgrowths of a fungus, very slightly differing, if at all, from *Cladysporium herbarum*, with here and there very distinct fungoid bodies, identical with *Macrosporium tomati*. The latter fungus is one of the causes of depressed blackish patches on Tomatoes at various stages of their growth, and commonly at the eye. Your plants are too strong—that is, the nitrogenic elements are overpowering the mineral, and a gross sterile habit is the consequence. We advise leaving a little side as well as top air on the house constantly, only supplying water at the roots to prevent flagging, and fertilising the flowers carefully about noon with a camel's hair brush when the flowers are fully expanded. This is tedious, and not always successful, as the plants are so gorged with crude material as to develop fructifying organs very imperfectly. Sometimes cross-fertilisation from different plants acts well, but the point is to either secure higher elaboration or supply more seed-forming material, such as mineral superphosphate 37 per cent., soluble, superphosphate lime three parts, double sulphate of potash and magnesia (48 per cent. of the first and 25 per cent. of the latter, with 2½ per cent. of chlorine) two parts, mixed, supplying 3 to 4 ozs. per square yard and washing in. If used in liquid form use half an ounce per gallon of water.

Peach Trees against Wall Unhealthy (E. B.).—Though Peach trees succeed against an east wall in the southern parts of the country, it is not a good aspect for them, as the easterly winds affect the tender foliage, and blister-fungus is the consequence. Peach-leaf and shoot blister-fungus, *Ascomyces deformans*, however, is quite independent of east winds, but these produce that condition of the tender growths peculiarly favourable to its development, and of which it is not slow to avail itself. The best safeguard against the parasite is efficient protection from frost and biting winds during the spring months, this being a necessity in outdoor Peach culture and too often neglected, hence the pitiful condition of many trees against walls. Of course, you will know that removing the affected parts by degrees is the approved means of getting rid of the damage, and as warmer weather comes the trees will grow out of the disease. If you dust the trees with an advertised fungicide containing 10 per cent. sulphate of copper, such as fostite and anti-blight, it will do much to prevent the production and dissemination of spores, but it will not destroy the mycelium in the affected shoots. We have found sewage of very great service, especially with 1 lb. of sulphate of iron added to each 100 gallons some time before use, so as to secure conversion into a double sulphate with the ammonia. There is no reason whatever why you could not lift the trees in the autumn, but whether it would be advisable is matter for your consideration. If very much decrepit and bare of branches, or even weakly and gummed in these, at the lower part of the trees, it may not be desirable; but if there is a fair amount of branches, and the trees are carefully lifted and replanted, we do not see why they should not improve, as is the case in many similar instances, and they have the advantage of young trees in that the cropping would not materially be interfered with. This is often a serious consideration, and ought to have the full approval of employers before being carried out. Even if you decide to plant young trees we should do so between the old, retaining these in part until the young trees commenced bearing, it being easy to cut away limbs so as to give room for advancing. This appears to us the wiser plan under the circumstances, as the old trees being weak and dying in the lower limbs, would have these cut away, whilst the strong upper parts would afford some acceptable fruit until the new trees afforded a good supply. Dry weather certainly causes roots to descend in quest of moisture, but we do not think chalk would hurt them unless surcharged with chlorine in consequence of the excessive use of the sewage; that, however, is not likely to have taken place.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (C. S.).—1, *Mertensia virginica*; 2, *Pulmonaria officinalis*. (O. A. T.).—1, *Saxifraga muscosa*; 2, *Anchusa italica*; 3, *Saxifraga granulata* flore-pleno; 4, Probably a *Thalictrum*, specimen insufficient for positive identification. (Y. S.).—1, *Pteris longifolia*; 2, *Asplenium biforme*; 3, *Pteris umbrosa*; 4, *Adiantum gracillimum*; 5, *Nephrolepis exaltata*; 6, *Nephrodium molle*.

THE DAY OF SMALL THINGS.

THINGS neglected, forgotten, or misused. Large matters receive attention, but the little things are left for anyone to do, or, rather, no one. What we want to do is just to point out in a very friendly manner a few little points worthy of the attention of every farmer. We know by experience it is most difficult to see to every little item that goes to make up the day's work; to watch that every man and boy is earning his full wage, to see that nothing is misused or spoiled.

The first thing we turn our attention to is the implement shed. No well-equipped farm is without many and costly implements, and on homesteads where the buildings are plentiful there should be no difficulty about housing implements not in immediate use. We remember on a large farm of our acquaintance there literally was no accommodation whatever except a corner in the stack yard, and the occupier had to take advantage of any bit of shelter afforded by a high hedge or straw stacks. This state of things had

existed during the lives of two tenants; the third man, who was of a very orderly turn, persuaded his landlord to remedy the evil, to the great benefit of the implements and to the general appearance of the premises.

Being on the subject of implements, shall we suggest a coat of paint is not costly, and a wonderful preventive of decay? Here, too, we exercise another little economy. We use long carts, with open sides, for harvest; they can carry a tremendous load, but lie idle except during hay and corn harvest. Wheels do not improve with drought, so off they come from the long cart, and are used for the ordinary farm vehicle, usually devoted to manure leading and general work.

In the stable, too, the fumes of ammonia from the horses is very destructive to gearing. Can the lads only be persuaded to walk a few steps to a rough saddle-room and hang each article carefully up, harness would have a much longer life. The same applies to an occasional cleaning, and oil makes leather supple, and causes the texture to resist the action of water better. "A place for everything and everything in its place." How annoying it is to see rakes and forks tossed about anywhere and anyhow. There are boys, and even men, who will never think of moving one step out of their way just to put a fork in a corner or hang up a rake.

On a farm there is a constant need for repairs (in woodwork). Troughs, tumbrils, gates, trays—i.e., hurdles, and a thousand other things too numerous to mention, are always needing "the stitch in time." If you are always sending down to the wheelwright's, whatever else he does, of one thing you are certain—a pretty long bill at Christmas.

We can remember in the days of long ago the carpenter's shop on our farm, and how our father with the aid of a clever foreman did all the repairs himself on wet days. We never bought a gate. They were all home made, and painted red to give a touch of colour to the landscape. Ah! now we touch another point. No gate lasts out half its natural life if badly hung—it knocks itself to pieces, and soon pulls the post out of plumb, and is a constant source of aggravation to every user.

There was a time when a farmer's great difficulty was to get all his straw trodden down into a semblance of manure. Those halycon days are fled, and yet we doubt if we have got over their effects. It is most difficult to get the ordinary farm labourer to economise either his straw or even hay, and how few will take the trouble to weigh out cake or other feeding stuffs. There is so much rule of thumb or guess work, and it is most of it in favour of the stock rather than the master. Far be it for us to wish to stint any live stock, but the hand-food they get is very valuable and costs gold, and it must not be treated lightly.

Have you ever, kind reader, seen in a neglected corner of farm premises piles of old wood? The remains of once fences, aged gate posts, hedgerow timber, not good enough for market? Have you observed how the heap unmolested grows, and how at the same time costly coal is used for steaming, threshing, and house purposes? A steam engine in conjunction with a circular saw for a day will provide out of that heap of waste a noble pile of excellent firing. Have you, again, ever seen in a dry season the water cart hard at work providing for thirsty stock? And have you, again, on the same premises on a winter's day heard the drip, drip from the eaves of all the buildings?

A friend who bought a property on the high wolds where water was always scarce, before he did a brick of building constructed an immense cistern, rightly assuming that with proper management winter surplus should help out summer drought.

Has anyone ever seen the leakage of valuable liquid manure from crewyard or cowhouse? The storage of Potatoes, Swedes, or Mangolds where every passing hen could pick her fill? How about that last load of engine coal, thrown in a corner? If not an actual temptation to a poor man, at any rate it does not increase exposed to wind and weather. Were all the thatch pegs carefully put aside ready for next harvest when that Wheat stack was stripped for threshing? and was the cord used in tying the sheaves laid aside for Potato and corn bags, or allowed to go in among the straw, indigestible as food, and not desirable as bedding?

It seems an easy matter to steam Potatoes (we mean on a large scale for stock, not the family tureen), but the generating of that steam may be made a cheap or costly affair, depending on the common sense, or want of it, on the part of the steamer—is there such a word? It is just the same with steam power used in any

department of farm work. There used to be men who perambulated the country and mended all sacks; it is a long time since we saw one. Either the sacks go unmended, or new ones are bought or hired.

Just two more points and we have done. Is it absolutely necessary to have such immense hedges in arable fields? Would not a strong well-grown quickset fence be even more effectual than that mass of straggling briar, bramble, grass and rubbish now dignified by that name? True, the country lanes might not be so picturesque, but economy before beauty, my friends. What, too about "garings" or headlands? Remember land so often trodden on is practically unworkable, and therefore unprofitable. There must be a little space left for Turnips, but let it be as little as possible. We cannot afford to lose an atom of crop; letting alone the unsightliness, it is the contrast between a fine Swede crop garnished with an edging of very inferior White Turnips.

WORK ON THE HOME FARM.

The last ploughings are completed, and the main crops of Turnips will be sown as soon as rain comes. If sown with the soil in its present dry state we doubt whether the seed would germinate; some of it might, but it is a bad thing to have uneven germination of Turnip seed; insect pests have more time in which to work destruction, and the labour of hoeing and thinning is much increased.

The land is now becoming decidedly warm as the result of the bright sunshine, and a good day's rain would put it into such fine condition that the seed would soon be up after sowing, and be much more satisfactory in the end than if sown now and coming up piecemeal. This has been the case with Mangold, which promises to be very patchy, the soil having been dry and rough in some places.

Prospects of winter fodder are becoming gloomier day by day. We hear of farmers beginning to stock their meadows, the grass being sorely needed at the present time; but how about the winter? It is hardly likely that Wheat straw will be a heavy crop, though the grain may be, and Barley and Oats must be very short in the straw unless the weather turns topsy-turvy and remains so until August. Another week of drought will practically ruin the prospect of even an average supply of fodder. Naturally prices are rising, and we hear of £155 being made of a stack for which only £70 was bid last autumn.

Potatoes are growing fast, and horse-hoeing progresses apace. The hand hoe will soon have its turn amongst them, the spring corn being now about looked over.

Ewes are being washed ready for clipping, and some people are clipping already. It is time the wool was off, but the winds have been very cold and might give the animals a chill, resulting in downfall, a most dangerous complaint to the sheep. There has been no trouble with maggots as yet; but it is maggot time, and for that reason the wool would be better off the sheep's back. Shepherding is so much easier.

OUR LETTER BOX.

Milk Fever (D. R. D.).—You do quite right in penning your in-calvers at least three weeks before calving, but you do not appear to give a purgative, which is highly necessary. Epsom salts and powdered aloes make the best mixture. With a cow on dry food or naturally costive nearly 1 lb. salts and from 2 to 4 drachms of aloes make a dose. One dose a fortnight before calving, a second two or three days before, and a third at, say, two or six hours after calving. Calve, if possible, in a fresh cow house, or at any rate limewash. We will treat this subject more exhaustively in an early number of the Journal.

23rd.—Bright and sunny all day; clear night.

24th.—Overcast early, gleams of sun about 11 A.M., and bright afternoon.

25th.—Generally cloudy, and hazy and close, but occasional sunshine. Spots of rain at 1.50 P.M. and in evening.

26th.—Overcast throughout; almost continuous slight rain or drizzle, from 8.30 A.M. to 1 P.M., and slight showers later.

27th.—Cloud, sunshine and showers; cloud preponderating in the morning and sunshine in the afternoon. Rain from 9.30 P.M. to 11.30 P.M.

28th.—Alternate cloud, showers, and sunshine. A little hail at 1.20 P.M.

29th.—Occasional sun early and about 4.30 P.M. Rain from 0.30 P.M. to 3 P.M.

The drought broke on the 25th, having lasted almost three weeks. Temperature near the average.—G. J. SYMONS.

LAINGS' BEGONIAS AND CALADIUMS

NOW IN FULL BLOOM AND FOLIAGE.

"THE PREMIER HOUSE."

Joyning's Nurseries, WALTHAM CROSS, N.

London Fern Nurseries,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracaenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—J. E. SMITH.

ORCHIDS.

CLEAN HEALTHY PLANTS AT LOW PRICES.

Always worth a visit of inspection. Kindly send for Catalogue.

JAMES CYPHER,

Exotic Nurseries, CHELTENHAM.

BEGONIAS

FOR BEDDING OR CONSERVATORY.

I have a large stock in fine condition. The quality is A1, and really worth double the money.

Finest Single Mixed, in all shades of colour, 12, 3/6; 50, 13/-; 100, 24/-.

Finest Single Mixed, in shades of Bronze, Orange, Copper, Fawn, &c., 12, 3/6; 50, 13/-; 100, 24/-.

Finest Singles, in 10 distinct colours, 12, 4/-; 50, 14/6; 100, 26/6. All the above can be sent in or out of pots as the purchaser may desire.

H. J. JONES, Ryecroft Nursery, LEWISHAM.

150 ACRES of Trees & Shrubs.

In the finest possible condition for the Villa, the Mansion, the Plantation, or the Game Over. All in vigorous, healthy condition, not stunted, starved, or closely grown and drawn. Carefully and frequently moved, and the roots consequently are a mass of fibre, ensuring safe removal when sold.

NEW CATALOGUE, with descriptions of above, and of many Rare and New Plants, Post Free from

CLIBRAN'S Nursery, ALTRINCHAM

Also at Manchester, Bangor, and Llandudno Junction.

Journal of Horticulture.

THURSDAY, JUNE 10, 1897.

PRODUCTIVE AND UNPRODUCTIVE TREES—BUD AND GRAFT INFLUENCE.

EXAMINING our Gooseberry bushes yesterday we found some well furnished with fruit and others with scarcely any, and this quite irrespective of sorts or of position. An old gardener near by said that the barren ones were struck from suckers (which grow round the stalk), and the fruiting bushes from the ends of fruit-bearing branches. I have myself had some suspicion of this before—viz, as in the case of Strawberries raised from barren plants. Can you tell me if there is good ground for the old man's theory? In many large nurseries they raise bushes from "suckers," which, however, is no proof at all.—T. W. BEATON.

[This letter opens an important subject, to which, perhaps, scarcely sufficient prominence has been given in the horticultural Press. This presumably means that careful tests have not been made in experimental gardens on the influence which buds and growths exert on the plant, bush, or tree of which they are chosen (if chosen at all) as the foundation. We have recently glanced over a remarkable Report by the Duke of Bedford and Mr. Spencer Pickering of the experiments conducted at what may be termed the Scientific Fruit Farm established by the Duke on his Woburn estate. We do not know how many scores or hundreds of experiments are enumerated in the Report (which has passed out of our hands), but we do not remember one bearing on the subject of growth characteristics, or bud variation, as predisposing to floriferousness or the reverse; yet it is reasonable to suppose that such experiments would be at least as likely to issue in instructive practical results as are several of those in operation, important as these may prove to be.]

We certainly think there is ground for the "old man's theory" relative to the cause of the unfruitful Gooseberry bushes. That the character of the cutting is largely represented in the resulting plant we think many, if not most, experienced gardeners know, and they select cuttings accordingly. If they covet robust growth and comparatively few flowers, they choose robust cuttings from leading growths; if they

prefer plants of bushy habit and floriferous, they select less vigorous side growths for producing them.

Rose growers, amateur and professional, who have been close observers for many years, we imagine know that buds taken from (a) enfeebled growths, (b) robust flowerless stems, and (c) sound healthy floriferous parts have differing results, corresponding with the inherent character of the stems from which they were taken. If this were not so, why should they be so careful to select the "best buds" obtainable?

Nurserymen know quite well that for producing free, upright growing Conifers and trees they must choose their scions from upright or terminal growths, because these "go ahead," whereas stunted side growths produce "dumpy" trees, with a tendency to premature flowering. We think also that old grafters of fruit trees know the influence that different kinds of scions exert on the continuation growth of those scions, and select accordingly. Those from luxuriant growths of non-fruiting trees are less likely to be so soon productive as others well chosen from fruitful trees and branches, the stocks and soil being the same in each case. We apprehend it is not difficult to produce mere stunted pigmy trees overlaid with fruit by the choice of buds alone, and other trees of the same variety on the same kind of stock by the side of them growing "like Willows." In a small experiment we have found that this was so exactly in that particular instance. We have also found, like Mr. Beaton, the unwisdom of perpetuating Strawberries from barren plants.

In raising Gooseberry bushes we should not take cuttings from robust sucker growths which had not produced flowers, as we should fear that such cuttings would tend to produce slow or sparsely fruiting trees. Nor should we choose the extreme tips of heavily fruited branches, at least without much discrimination, as many of such parts are too enfeebled and apt to produce weakly stems and leafage so tempting to the destructive mite known as red spider. Cuttings from sturdy bearing shoots on which the leaves have been fully exposed to the sun are such as we prefer, removing the tips down to the "best buds" before the cuttings are inserted.

The subject of the character of growth and buds influencing subsequent growth seems to have received more attention in America than in England; and Mr. L. H. Bailey, of the Cornell University, records in his book, "The Survival of the Unlike," lately referred to in these columns, that "every farmer's boy knows the reddest and earliest Apples grow on the uppermost branches, and his father always tells him that he should never select scions from the center or lower part of a tree." In the old country "every father" who may have fruit trees does not give his son such good advice, because only comparatively few fathers have themselves been taught the significance of the lesson.]

CONSERVATION OF SOIL MOISTURE.

MULCHING.

MOST welcome is the long-expected rain; though in some districts it has only partially effected its purpose, yet it has refreshed vegetation greatly, and it behoves us to make the most of what has fallen by every means in our power, lest another period of drought should be experienced. The long continuance of the parching easterly winds had a disastrously drying effect upon some soils. Fortunately heavy dews have helped to refresh the foliage of trees and plants at night and early morning, but when these have been followed by bright days, with strong winds sucking the moisture out of the leaves, the good effects of the dew have been of short duration. Some bush fruits, especially Gooseberries, have suffered the most, and the crop being generally so short one cannot afford to lose any more; yet the berries have fallen by scores in some places, and they do not appear to be much worse on light soils than on heavy ones—at least, as far as I have observed, there is little difference. The drying wind produced an immediate effect on the foliage and growth, against which the roots were unable to fortify the plants without further aid than the ordinary soil stores will supply. I have to deal with a heavy soil which is of a most peculiar nature, as it cracks greatly after a

few days drought has been experienced, and constant hoeing, while reducing the tendency considerably, yet does not suffice to prevent the cracking assuming a serious form. All who have had much experience are most reluctant to commence supplying water to plants of any kind out of doors, for when once begun it must be continued, and not sparingly either, or the mischief resulting is greater than the remedial effects. The constant watering of large numbers of plants in the flower or kitchen gardens means an enormous increase of labour, and there are few establishments where this would not cause a serious interference with pressing routine work.

Much can be done at the present time to minimise such labour, and one of the readiest means is securing a thorough surface tilth by means of the hoe. The use of this instrument for surface stirring is beneficial even in dry weather, but there are some soils upon which it can scarcely be used with advantage in periods of drought, because the superficial layers become so hard and baked that the hoe will make little impression. A moderate rain, however, renders it workable with ease, and the operation should be pushed forward rapidly now amongst growing crops of all kinds. This refers merely to stirring soil to the depth of about 1 inch, but where it can be done without injury to the roots of plants light forking to the depth of 4 or 5 inches is even more beneficial, particularly as regards retaining the moisture in the lower portion of the soil for trees or deep rooting plants. For the purpose in view there is a limit to which soil stirring can be carried with practical benefit, and it has been found that beyond 6 inches no appreciable effect is produced in the conservation of moisture, and for all ordinary crops 4 inches is the extreme, while stirring even half an inch in depth produces a marked effect.

The capacity of different soils for water varies greatly, as also do their powers of retention. For example, it has been found by experiment that while 100 parts of sand will absorb 25 per cent. of moisture, yet out of 100 lbs. of water so absorbed there evaporated in four hours, at a temperature of 66° Fahr., no less than 88 lbs. In the same way, loamy clay absorbed 40 per cent. of moisture and lost 52 lbs. in the same time as the above, heavy clay absorbing 61 per cent. and losing 35 lbs. of moisture. But the most striking difference is shown in the case of rich garden soil and humus, the former absorbing 96 per cent. and losing 25 lbs. of water, the humus taking up 181 per cent. and losing only 21 lbs. of water in the four hours at the temperature named. The condition of the soil, therefore, which will most readily help in the conservation of moisture is a well-worked surface containing an abundance of humus—i.e., decayed vegetable matter—as a relatively larger quantity of water is absorbed and a smaller proportion evaporated.

It is evident that, for the above-named reason, farmyard or stable manure would have a better effect in increasing the water-holding power of the soil than artificial manures; but to prove this point some experiments were undertaken at Rothamsted, which showed the effects conclusively. The observations were made in a wet winter, when samples of soils treated with farmyard and artificial manures were taken at different depths, and the amount of water carefully determined with the following results:—

Farmyard Manure.				Artificial Manure.			
		Per cent.				Per cent.	
1st—3 inches of soil	39.7	1st—3 inches of soil	26.5
2nd "	"	...	35.6	2nd "	"	...	22.9
3rd "	"	...	28.9	3rd "	"	...	20.6
4th "	"	...	24.0	4th "	"	...	24.7
Average	32.1	Average	23.7

It is interesting to note that the superficial layers only were influenced by the different manures as regards their water-holding properties, and at a foot depth the effect was practically inappreciable.

Mulching is a time-honoured practice to aid in the preservation of soil moisture, and its utility has been so repeatedly proved in a general way that it is not surprising it should be so commonly adopted. Much advantage accrues, in fact, from applying a good dressing of short litter—straw, grass mowings, or any similar substance around trees or plants at this time of year, especially after rain. Nor is a heavy mulching needed if the soil has been well worked, for it has been proved by comparative experiments that a very slight application of this kind to the surface will have a greater effect in insuring the retention of water than stirring the soil 4 inches deep, and a mulching 1 inch in depth has almost double the effect of soil stirring alone.

If plants or trees are weakly the mulching can take the form of a manure dressing; or what is even more effective in some cases, the manurial aid can be given in liquid form. After a rain like we have had is the best time for such assistance; it is almost useless, and certainly very wasteful, to supply liquid manure when the soil is parched with drought. It is better even to give a liberal supply

of water first, to be followed by the manurial liquid, than to attempt giving the latter while the soil is dry. Another point, too, that is in danger of being overlooked is the importance of supplying liquid manure in a weak state and frequently, rather than in a strong form and more seldom. Far greater satisfaction results from such treatment, as the plants can appropriate the food constituents more readily, and there is not the risk which arises from strong applications.—PRACTITIONER.

PLANTING CELERY.

CELERY is a most important kitchen garden crop, and requires special attention during the early stages of cultivation, so that growth may be steady, regular, vigorous, and healthy. The plants should receive at all times abundance of light and air for the foliage, with constant moisture to the roots. Without a free supply always available to the numerous roots, the food in the soil and manure, however adequate, cannot be made sufficiently soluble and usefully appropriated. Water itself contains some food the plants want; but in addition to supplying this, it has the great function of rendering soluble the necessary salts required for the sustenance of Celery as well as other plants. Celery is a great absorber of moisture, hence it is essential that due provision should be made to meet this demand.

The importance of moisture commences to be apparent when the young plants have been pricked out from the seed pan or boxes. The roots increase rapidly in a suitable medium, and the plants grow freely. Growers of Celery are aware of this, and provide a rich, light, and moist root run, such as the young plants can revel in. The half-spent hotbed surface, with a few inches of light rich soil, is usually a favourite place where seedlings are prepared for the final planting. A layer of manure on a firm bottom in a frame and over that soil, the bed being near the glass in every case, is also suitable. Plants having thus been cared for during the preceding month, are ready for the trenches in June.

Later sowings may receive more hardy treatment, but the soil for them ought also to be rich and moist. This, however, can be insured by digging in, previous to pricking out, a liberal dressing of decomposed manure.

In selecting a site for growing Celery a situation may be chosen where the ground is naturally rather poor, but light in texture rather than heavy and too retentive of moisture. Light and poor ground may be enriched for the growth of the Celery, but soil retentive of moisture to an undue extent is not readily drained in a short period. The situation should be open, unobstructed light and a free circulation of air being essential in promoting a sturdy growth which can endure the vicissitudes of an ordinarily severe winter.

The best method of planting Celery—except, perhaps, under special circumstances—is in single or double trenches 4 feet apart. They can run in a N. and S. direction. The width of the trenches may be 18 inches for double rows, and 15 inches for single. The soil ought to be taken out to a depth of 15 or 18 inches, filling in about a foot of manure. This should be well decomposed cow manure, or general farmyard manure well decayed. If the subsoil is good a portion of that may be mixed with the manure in digging the latter in; but some of the better material thrown out on the sides must also be employed. Deep trenches with sheer perpendicular sides are not now tolerated. Trenches comparatively shallow when their preparation is complete are the rule. They are warmer, more exposed to light, and can be watered to better effect. Their improved appearance is also a recommendation.

Before lifting the plants for final planting in the trenches they ought to be well watered, or a period selected when thoroughly moist. Dull weather is to be preferred for planting, and each plant must be raised from the bed with a good ball of roots and soil, an easy matter when proper methods in preparing the plants have been followed. The distance between the plants may be in single rows a foot if large sticks are required. Ten inches asunder is a useful distance both for single and double rows, a foot distance in the latter not so frequently being employed. Trim off all small leafstalks and short suckers appearing at the base. There will be less trouble from them afterwards.

Plant just a little lower than previously, forming the holes to receive the plants of ample depth and width. Render the soil firm about them, and preserve them from flagging by planting quickly. The drying influences of the air soon abstract the moisture from the soil about the roots should the plants be exposed for an extraordinary length of time. Hence it is not desirable to lift many at a time. Whether water will be required immediately after planting or may be deferred depends on the weather and the state of the soil.—E. D. S.

POINSETTIAS.

As a plant for winter decoration *Poinsettia pulcherrima* stands without a superior. Its bright scarlet bracts are practically indispensable for the adornment of dining table and drawing-room, and coming at a time when flowers are scarce an additional charm is added. No other inmate of the stove or greenhouse possesses such a brilliancy of colour, or one which shows to better advantage under artificial light. Used in conjunction with Roman Hyacinths or other white flowers the contrasts blend in an harmony that is at once elegant and pleasing. To dwell long on these points, however, is but to repeat the plant's oft-sung praises, and when we think of them and their usefulness it strikes us as being somewhat remarkable how rarely we see *Poinsettias* really well grown. It is one thing to obtain plants with small straggling bracts surmounted on almost leafless stems, and quite another to have them nearly a foot across, compact in form, and with stems clothed to the pots with healthy foliage. These are the specimens that delight the decorator and do credit to the grower. There is no secret in the method of their production. It is the old, old story—suitable conditions of culture and close attention to detail, and in this short phrase we have the law of successful gardening.

Just now the process of propagation is in full swing. During the early months of the year the plants have been in a resting condition. In most gardens the dried sticks have been shaken out of the old soil, repotted, and are now pushing numerous side growths under the genial conditions of forcing house or pit. Cuttings inserted now and grown in a cool house or frame close to the light, make dwarf sturdy plants, warranted to carry creditable bracts in the winter. They are, however, somewhat fastidious about rooting, and have a great tendency to damp off. A frame in the propagating pit is the most suitable place for them, and the cuttings should be formed of the short sturdy growths, preferably with a heel of the old wood attached. It is well to let the cuttings lie for half an hour before inserting them, in order that the wounds may be dried somewhat, after which they should be placed singly into thumb pots, watered, and plunged in a brisk bottom heat. For the first few days they require a dense shade during the hours of sunshine, gradually inuring them to the light.

As a rule the insertion of cuttings formed of long-jointed, sappy growth will only result in failure; but if proper, well-matured, and short-jointed growths are chosen they will root in ten days or a fortnight without losing a single leaf. It is easy to tell when the tiny plants have commenced growing at which stage they should be removed from the hotbed and kept close to the light in order to prevent drawing and lanky growth. Potting as required must not be neglected, otherwise if the plants are allowed to suffer for want of water the lower leaves assume a yellow and sickly appearance, which is a condition one naturally wishes to avoid.

The treatment of old plants differs somewhat. Where required for room decoration it is often desirable that they should be tall, hence the necessity of growing them in heat. After the old plants have been potted and growth has commenced it is best to take off the upper shoots for forming cuttings, leaving the lower to develop into bracts. By this means it is possible to obtain plants of a bushy character, having three or four or even more of their bright clusters of scarlet tops. Light is the principal requirement, as the growth must be well matured. *Poinsettias* are often grown in stoves amid other plants and under creepers, but the results are invariably unsatisfactory, as the stems are elongated and sappy, possessed of insufficient stamina to produce and mature large heads. Growing the plants in heat has its advantages and disadvantages. Fine bracts may be obtained in this way, and one of the best collections I ever saw in this respect was grown in a house of stove temperature and the pots plunged in a bed of leaves. The plants were tall and strong, and in the house presented a fine appearance, but when cut or taken out in the pots the leaves felt the change and turned flabby and limp.

The question is sometimes asked how to grow dwarf plants having good bracts, for after all the *Poinsettia* in this condition is the most serviceable. In the first place they must be grown cool, in order to insure dwarf habit and green leathery foliage; secondly, they require abundance of light, hence the necessity of growing them close to the glass. It is the custom of some growers to allow their plants to start naturally at this time of the year, keeping them in cold frames till cold weather sets in, then removing them to a warm structure for flowering. Old plants may be so manipulated that, in conjunction with free dwarf habit, three or four good bracts may be obtained on a plant. Those rooted in the spring in the manner suggested only produce one bract each, but usually these are so much finer, and the plants so well furnished with leaves, that it is advisable to depend chiefly on early summer propagation, particularly if dwarf specimens are required for decoration.

After the young plants are rooted they should be removed to

cold frames, and will be all the better if the pots can be plunged in some suitable material which conserves the moisture. Thus the risk of dryness at the roots is diminished, and there is less fear of the lower leaves dropping or turning yellow. As rooting increases the plants should be removed into 6 or 7-inch pots, these sizes being large enough for the main portion, though later-rooted plants may be confined to 4 and 5-inch. An ordinary mixture of loam, leaf mould, and silver sand will be found suitable, and in the case of the largest pots it is a good plan to leave sufficient room at the top for a dressing of rich compost when the plants are forming their bracts, as this increases the size and improves the colour considerably. On bright sunny afternoons the plants should be syringed and the frames closed, thus changing the atmosphere of the structure into that of a miniature stove, by which means the sun heat is conserved, and a genial condition suitable to the welfare of the plants is obtained.

Watering is an important matter, as the foliage will turn yellow from either drought or excessive moisture. Both extremes must therefore be avoided, as the losing of leaves robs the plants of half their beauty. When the pots are well filled with roots liquid manure may be used with advantage; and if soot is used in the formation of this it assists greatly in giving a dark green hue to the foliage.

On the approach of cold nights the plants must be removed from the frames, and given the accommodation of a warm house, growing them close to the light, and avoiding a sudden change into a dry arid atmosphere, otherwise the foliage will inevitably suffer. To be successful in the cultivation of this useful winter plant a few simple rules should be laid down, and strictly adhered to. The plant wants no coddling, but will not brook neglect. Close attention is the chief factum, and this given the cultivator may be rewarded at Christmas time with an abundance of rich scarlet bracts, suitable for the beautifying of conservatory or drawing-room.—G. H. H.

HORTICULTURAL HISTORY NOTES.

ALONG WESTERN MIDDLESEX.

SEVERAL circumstances lead us to think that in what some folks call the good old times, when daily newspapers were small and expensive, when gardening could not boast of a single journal, gardeners of all sorts must have been very sociable with each other, or otherwise they could not have gleaned the information they did on various points. No doubt they had to make efforts to overcome the stiffness which characterised English life till quite recently. Had it not been thus there would have been a serious bar to the distribution of new plants and varieties, which must otherwise have only been known within a narrow circle. Again, a country visitor, wishing to get an insight into London horticulture, would have been badly off had he been obliged to limit himself to the few public gardens accessible. Through friends he could enter various private grounds to which gardeners were admitted by favour, or even, occasionally, promiscuous visitors. Of these at one time there were many about the metropolis. Some of them have disappeared; probably of those now remaining the owners have to exercise more caution than formerly in admitting strangers, lest a privilege should be abused.

Looking back fifty years ago, no farther than that, to the period when Victoria was still a youthful Queen, and busy not only with State affairs, but the cares of a young family, the visitor to London found most of its attractive gardens upon the western side. Having examined the nearer of these, going, of course, to Clapham in Surrey, which, even till 1845, was famous for its gardens and park-like demesnes, also viewing those of Kensington and Hammersmith in Middlesex, he would naturally follow the valley of the Thames, seeking out gardens along its green banks or upon the higher ground at no great distance westward.

Leaving Holland Park on the south, with its goodly gardens and historic trees, crossing the crown of Notting Hill, the stroller may pass Shepherd's Bush, suggestive of the time when numerous flocks of sheep grazed on the fields hereabouts, and traverse the road to Acton and Ealing. That the name of Acton meant "Oak town" there is no doubt. The place was once within, or on the edge of, an Oak forest. In this century it served as a refuge for some market gardeners, when the nearer suburbs became a prey to the builder. Beyond it is Ealing, now fast losing its rural character. At first the name was "Yelling," of uncertain meaning, a locality which, both in soil and atmosphere, is very favourable for horticultural pursuits. Visitors to the neighbourhood half a century ago used to discuss whether Ealing Park or Gunnersbury was the more to be admired; the latter being chiefly laid out by Kent, having 70 acres in its grounds originally, while Ealing Park, somewhat less, showed the handiwork of Brown, improved by Repton.

When Orchids were comparatively novelties in English gardens,

Gunnersbury was famous for the display it made of these species. The large Orange trees grouped in the orangery were also an attraction; there were two very tall Tree Ferns, and an old, large Liriodendron. A cluster of venerable Cedars attracted notice, round the trunks of which were circular beds of Ivy, which also encircled other trees, and this practice was copied elsewhere by some who visited Gunnersbury. The lakes were contrived by Kent so as to afford good prospects of land and water, while they had a fine fringe of trees. Though not horticultural, a collection of sandstone figures in a temple near the circular lake were always sought out. They exhibited a series of scenes in the "Beggar's Opera." The principal flower garden was circular, surrounded by trelliswork, an outer circle having assorted climbers, the inner one Roses. Numerous stoves and forcing houses had a large display of exotics.

Ealing Park had at one time the honour of taking off prizes at nearly every flower show held in the neighbourhood of London, no trouble or expense being spared. The conservatories were large, and most of the newer species or varieties could be seen to advantage. The ornamental water was placed in a dell, around it evergreens occupied the rising ground, also rockeries and banks of Fern; an opening was made on the side of the park, to afford a view. What were called the Italian walks gave a reminiscence of the doings of "Capability Brown," who planned a lawn in front of the house, which was planted chiefly with Conifers, and from which avenues branched off; one of these had fine specimens of Cupressus macrocarpa. Near the mansion Garrya elliptica was conspicuous with its flowers, and Arbutus procera with its late fruit. Most of the flower beds at Ealing Park used to be placed in grass.

At a more recent date, Ealing Dean has had some fame through a possessor of the familiar name of Smith, a large grower of Cyclamens and Poinsettias; his Begonias and Solanums have also been widely distributed. Spring-flowering plants, such as Primulas and Pansies, have attracted many Londoners to the Ealing district. Near Acton, Mr. Reeves has made a speciality of Tulips, importing and growing many thousands yearly. Other nurserymen still hold their ground between Ealing, Brentford, and Turnham Green in spite of modern "improvements."

Going higher in the course of the Thames, after Kew had been duly visited, a natural curiosity would lead a gardener fifty or sixty years ago to seek admission to Sion or Syon House, of which he would have heard as a notable establishment, linked historically to the ducal families of Northumberland and Somerset. It was one of the places where the skill of Phillip Miller, so long connected with the Apothecaries' Chelsea Garden, was seen in operation. Long before his time there existed a botanic garden at Syon, when England had very few of these, and the Duke of Somerset took some trouble to procure exotic species. One of the heads of the establishment was a James Meader, afterwards gardener at St. Petersburg to the Empress Catherine, the author of a book he called the "Modern Gardener," or "Universal Calendar." He was also given to verse writing of a satirical character, and in his effusions frequently attacked both friends and foes.

The flower gardens at Syon House had some good Roses and many interesting herbaceous plants, while on the lawns were choice specimens of several of the rarer shrubs; but the houses presented the principal attraction. Built during a period when metal roofs were little known and much suspected, the numerous forcing houses, constructed of iron with copper sashes, stood the test of time well. These were placed in the kitchen garden department, some of them being set apart for tropical fruits. A special house was devoted to the Victoria Regia and species of Nelumbium. It used to be the custom at Syon to maintain a rather high temperature with an abundance of moisture, so that plants fruited there which did not elsewhere; and to some extent these houses initiated a change in this respect. The grand series of conservatories were erected in the form of a crescent, the centre rising to a high dome, and the end houses also being loftier than the sides, the structure consisting of stone combined with iron and copper.

Twickenham is hardly to be styled a London suburb, yet its memories connect it with the history of the metropolis, especially, too, with Bacon, the father of modern natural science, who once owned the park; "a pleasant place to study in," said he, and doubtless it was. A variety of accounts have been given concerning the first cultivation of the Weeping Willow in England, but the most probable statement is that the original tree was received from the Euphrates by Mr. Vernon, occupier of the park in the reign of George II. Near Twickenham a private botanic garden was started about 1789 by Mr. Swainson; he had some flowers, but aimed principally at cultivating every tree and shrub which would flourish in our climate. Fifty years since or so the garden of Cambridge House, just above Richmond Bridge, was visited for its collection of stove plants and Pelargoniums. It had an orangery, and the grounds contained many fine old trees.—J. R. S. C.

ODONTOGLOSSUM CRISPUM STARLIGHT.

THE number of *Odontoglossums* staged at the recent Temple Show was very considerable, and it is perhaps needless to add that many were of exceptionally good quality. The majority of the plants staged were forms of *O. crispum*, and amongst these the variety *O. c. Starlight* (fig. 96), staged from Mr. R. Brooman White's famous collection at Ardarroch was quite one of the choicest. The handsome spike carried several beautifully formed flowers of most distinct colour. The sepals are deep rose profusely spotted with brown, while the petals are white suffused with rose, and spotted similarly to the sepals. The lip is white, sparsely spotted with chocolate, and the throat is yellow. The Orchid Committee of the Royal Horticultural Society awarded it a first-class certificate.

ORCHIDS AT THE TEMPLE.

EXCELLENT as are the exhibitions annually held at the Temple, probably at no other show has there been such an array of good things in the way of Orchids. The number shown perhaps was not greater than other years, but the quality was certainly better than ever. *Cattleya Mossiæ* was in grand form. Prominent was the lovely pure white *C. M. Wagneri*, the most chaste and pure of all the labiata section of *Cattleyas*. The only spot of colour on this superb form is a yellowish area about the throat, beautiful in itself and serving to enhance the purity of the outer segments.

There was also a grand plant of *C. M. E. Ashworth*, a very distinct variety with a decided tint of blue on the lip. *Odontoglossum Queen Victoria* is a grand acquisition, the immense flowers having prettily flushed sepals, petals and lip, all having huge blotches of bright chestnut red. The plant had one spike carrying eight of these fine blooms, and was most deservedly awarded a first-class certificate. It was a happy idea to show *Phalaenopsis intermedia Portei* and *P. i. Brymeriana* together, the difference between the two being very marked.

The lovely and striking *C. callosum Sandersi* from Baron Schröder was in splendid order. The blossoms of this superb plant have lost all trace of purple, and are composed wholly of green and white in soft and beautiful combination. The splendid hybrid *Lælio-Cattleya Digbyana Mossiæ* was also shown, and this is perhaps the most striking instance of the hybridist's art. If Mr. Seden had raised no other hybrid than this he would have rendered a splendid service to horticulture.

Probably the finest new hybrid shown was *Lælio-Cattleya Lady Wigan*, a large and beautiful flower, the result of crossing *L. purpurata Russelliana* and *C. Mossiæ aurea*. The sepals and petals are white with a rosy suffusion, the immense basal lip beautifully frilled, the throat lightly spotted on a yellow ground, the front striped with crimson purple. Mr. Brooman White of Ardarroch had a form of *Odontoglossum crispum* called *Starlight*, and this is the most distinct form ever exhibited. The segments are rosy white, closely covered with small dots of crimson. *Lælia purpurata Ashworthiana*, though not quite new, is absolutely unique. Both petals are marked with crimson purple as deep in colour as that of the lip, and this variation from the type has proved to be constant. *Anætochilus Sanderiana*, *Stenoglottis fimbriata*, and *Cattleya Mossiæ Reineckiana*, from Messrs. Sander & Co., the lovely crosses obtained by Mr. Chapman between *Cypripedium bellatulum* and *C. Curtisi*, and bearing the name of this very successful raiser, are only a few of the more striking things exhibited, but as a full and excellent report has already appeared in the *Journal* I must not further trespass on the space.

AT MR. W. BULL'S.

The annual exhibitions of Orchids at Mr. Bull's are events anxiously looked forward to by those interested, and anyone who has the good fortune to be personally conducted by this veteran orchidist cannot fail to pass a very pleasant and instructive hour. The present is the sixteenth consecutive season of the show, and the multitude of good things to be seen should tempt anyone who has time to pay a visit. Grand forms of *Cattleya Mossiæ*, *C. Mendeli*, and others now in bloom, combine with the noble *Lælia purpurata* in forming a groundwork, while the lovely *Miltonia vexillaria* is seen in magnificent form.

Odontoglossums are always a strong point here, and this season is no exception to the rule. *O. c. stupendum* is one of the very best of the white forms that are to be seen here in abundance,

while other plants in this section capitally done are *O. hystrix*, *O. cuspidatum*, *O. polyxanthum*, and a host of others. *Miltonia Roezli*, *M. R. alba*, and *striata* are fine, while a splendid form of *Thunia Bensoniæ*, named *Winniana*, deserves mention because of its distinctness and deep colour. *Cœlogyne pandurata* is a quaint but delightful plant, the quite black markings on a bright green ground giving it a most distinct and unusual appearance.

Fine forms of *Oncidium Kramerianum* help to give lightness and grace to what is undoubtedly one of the most tastefully arranged houses of Orchids ever arranged, while *O. macranthum hastiferum*, *O. Marshallianum*, and other more showy kinds are freely intermixed. Besides the more popular and showy kinds there is a large and varied assortment of quaint and singular plants seldom seen. *Pleurothallis* in variety, *Masdevallias*, *Bulbophyllums*, and some of the tiny *Oncidiums* need only be mentioned. Hardly in the latter category are *O. pulchellum*, *O. tetrapetalum*, *O. phymatochilum*, and *O. pulvinatum*; but of all these species fine plants are in flower. In fact, there is hardly a known kind that blooms at this season that one cannot find well represented in this superb and varied collection.

AT MESSRS. J. VEITCH & SONS'.

In this well-known establishment the Orchids are now superb, the large *Cattleya* house being especially well filled with striking

FIG. 96.—ODONTOGLOSSUM CRISPUM STARLIGHT.

and beautiful forms. The collection includes some extremely fine dark forms of *Lælia purpurata*, which with *Cattleya Mossiæ*, *C. Mendeli*, *C. Skinneri*, and *C. intermedia* among others make a grand display.

The lovely hybrid *Lælio-Cattleya Hippolyta*, *L.-C. ascena*, with their delicate shades of orange and purple, are in full flower, while the rather better known *Lælia Latona* was flowering freely. In the charming little annexe where Orchids and Ferns are grouped in a pleasing and natural manner there were many choice things, including the pretty bigeneric hybrid *Epiphronitis Veitchi*, raised here by crossing *E. radicans* and *Sophronitis grandiflora*.

Fine plants of *Maxillaria Sanderiana* and the pretty *Disa Veitchi*, *D. grandiflora*, and *D. racemosa* were also noted; while in an adjoining structure *Oncidium pulvinatum*, suspended from the roof in baskets, had a pretty effect. The distinct *Dendrobium litiuiflorum* was represented by well-flowered plants; while possessing the cooler structures *Odontoglossums* in variety, and *Masdevallias* of the showy flowered section, were as conspicuous by their fine health as their freedom of blooming.—H. R. R.

MANCHESTER AND NORTH OF ENGLAND ORCHID SOCIETY.

THE second meeting was held in the Coal Exchange on June 3rd, the exhibits being much more numerous than at the previous meeting, and of the highest quality. There were some fifty-nine exhibits sent for inspection by the Committee, five F.C.C. and twelve A.M. being granted. The trade made a splendid display, Messrs. Lucien Linden & Co., Brussels, showing *Cattleya Mossiæ* in extra choice variety, a fine specimen and variety named "Queen's

Jubilee; Cattleya Mossiae "Goliath" (A.M.); Odontoglossum Pescatorei expansum; Odontoglossum Princess of Wales, a natural hybrid, very choice, after the way of luteo-purpureum (A.M.). Messrs. F. Sander & Co. had a most interesting group, including the curious and rare Bulbophyllum barbigerrum (botanical and cultural certificate), Cattleya Mossiae Princess of Wales, Lælio-Cattleya "Fire Queen," a brilliant flower of unknown parentage; Lælio-Cattleya D. S. Brown, Cattleya Trianae × Lælio-Cattleya elegans, Lælio-Cattleya elegans var. Novelty (A.M.), and Sobralia macrantha alba (F.C.C.).

Amateurs again showed their great interest by coming forward with many good things from their collections. A F.C.C. was granted to Mr. E. Shill, gardener to G. W. Law Schofield, Esq., for Dendrobium Bensoniae alba. Mr. Alex. Hay, gardener to G. Shorland Ball, Esq., Alderley Edge, showed in fine form Anæctochilus Sanderianum and Cypripedium Curtisi giganteum. Some beautiful specimens were staged by W. Gumble Groves, Esq., Alderley Edge, including an intensely coloured form of Dendrobium Falconeri (A.M.). A F.C.C. was unanimously granted for a model plant of the difficult Dendrobium Lowi. A cultural certificate was awarded for a fine specimen of Thunia Marshalliana, Miltonia spectabilis radiata having the title, "Grove's variety," affixed to it by the Committee.

Mr. J. Lucas, gardener to R. Wigfull, Esq., Ash Grove, Sheffield, sent Odontoglossum crispum Stonei; Mr. McDay, gardener to Duncan Gilmour Esq., Sheffield, sent two pretty forms Cattleya Mossiae Reineckiana, Gilmour's variety, and Rosy Queen; Mr. Edge, gardener to J. Leemann, Esq., Heaton Mersey, sent Cattleya Mossiae Constance Leemann, and handsome Lælia purpurata, a fine dark variety certain to improve, being named Leemani, being given an A.M. Mr. G. Shiner, gardener to E. J. Sidebotham, Esq., Erlesdene, Bowdon, sent a capital form of Cattleya Mendeli; Mr. Nicholson, gardener to D. B. Rapport, Esq., Mere Bank, Liscard, easily won a F.C.C. with the handsome Cattleya Mossiae Rapportiana, mentioned in the Manchester Whit Show report (see page 512).

Mr. Spurr, gardener to H. Greenwood, Esq., showed an excellent plant of Cattleya Mossiae, var. H. Greenwood; also fine Dendrobiums in variety. The exhibition was in every way a great success. G. Shorland Ball, Esq., has been unanimously elected Vice-chairman of the Society and Committee, and E. J. Sidebotham, Esq., J.P., M.B., Hon. Treasurer, vice Mr. Ball. All who know these gentlemen will feel confident that no better choice could possibly have been made.—R. P. R.

PRECEPT AND PRACTICE.

"SCIENTIFIC AND PRACTICAL COMPETENCY."

(Continued from page 476.)

THIS sub-heading is quoted from Mr. Older-Boy's precepts, given for our mutual guidance, and which, as will be recollected, were detailed and acknowledged in commencing these papers. Science is the ladder by which we mount above the drudgery of labour, and from the eminence command the forces of Nature. It is not sufficient that young travellers should follow mechanically in the tracks of pioneers, revealing the hidden ways; few indeed would find satisfaction in taking all teaching as an accepted fact without some endeavour on their own part to supply the proofs, and in the doing we form a higher appreciation of those privileges they have conferred upon us, as well as an intelligent interpretation of the lessons. Judging, however, by such evidence as is adduced in the "Domain," there is good reason for supposing that our young men will not only mark and learn, but inwardly digest; the necessity of the latter they will no more overlook than its value could be over-estimated.

It is not only a question of soil, heat, water, and the stores generally in Nature's laboratory, these we have always had, it is all these, and more also; it is the controlling hand of a great engineer, who in driving a thing of life and power understands its intricate anatomy and delicacy of detail. From the higher intelligence springs deeper sympathies with the objects of our care in this the kingdom of silent life, and from this results are obtained incomparably superior to the exercise of mere brute force. Apart from these principles, and their direct dealing in the making of gardeners, there is a strength derived from the exercise which makes men. Doubtless many, at least, of our petty vexations would vanish in the acknowledgement of laws immutable, which, seen or unseen, known or unknown, govern all things, for we more often transgress from ignorance than from design. Given but an elementary conception of those grand laws which rule the objects of the solar system poised in space, it must prepare one to find the same great cause working out the same perfection, even to microscopic atoms on our planet.

Dr. Lindley said, "In no departments of natural history are the simplicity and harmony that pervade the universe more strikingly manifest than in the vegetable kingdom . . . and the most important phenomena are distinctly explained by a few simple laws of life and structure." "Simplicity and Harmony!" The more we reflect upon this the more must the sublimity of our subject impress itself upon us. It will strike many that there is a great gulf fixed between the life of a botanist and the life of a gardener, as such respectively. That, I venture to say, is the case. Possibly we can do but little more than bridge this chasm by such means as an elementary text book on botany will afford. This has been mentioned before, so is merely repeated in order to introduce its twin pillar springing from the foundations of our faith, upon which is superimposed the whole structure of intelligent cultivation—viz, vegetable physiology.

Very probably any serious considerations of either of these matters will, for obvious reasons, only enter into a young gardener's life as recreative objects. They may well do so. I know that our young men may do worse than wield the willow or hunt the football on a fine summer's evening; but they will, surely, do infinitely better by keeping in sight the goal of a gardener's life, and making all their recreative runs towards it. Perhaps with most of us in early life it is the only way with which science can be sandwiched with practice, and serve as mental food to physical labour. "More precept than practice?" That is so. I would fain leave impressions by repeated hammering upon material while it is malleable even to the extent of older boys and better men viewing them as redundant.

The chief object of Nature is perpetuation by reproduction. In plant life and under favourable conditions invariably by seeds (other methods of reproduction will be considered). To regard seeds, those which come under our hands as embryo plants in which vitality is only arrested until set in motion by an exciting cause is, I think, a common-sense view conducive to successful germination, the minimising of failure, and rational treatment generally. In the earliest stage of plant life, the delicate embryo is nourished by a tiny store of food enveloping the germ during the hatching process, pretty much the same taking place during the incubation of an egg. The same wise provision we find afforded by other means in the animal kingdom prior to a separate existence between parent and offspring. Seeds having, of course, when properly matured on the parent plant an independent being.

When sound seeds are subjected to moisture—water and heat—the awakening commences, according to the individual character of the species, owing to chemical changes produced by those agents—water and heat, which heat may mean anything above freezing point, where all life is again arrested. From a superficial view there are apparently strange anomalies in Nature, which would probably disappear under a little careful observation. For instance, the natural method of propagation by seeds is, of course, the falling off from the parent plant with the indirect means afforded in manifold ways for distribution, germination, and successful development of all which we may call chance work, and for which due provision is made by lavish production.

From personal observation of some things, the Nasturtium, for instance, we may note how year after year natural sowings are made, in which apparently unripened seeds, left to take care of themselves, fulfil their mission unaided and in seeming contradiction to facts advanced. One border I know of is yearly adorned in this way by a luxuriant growth of many coloured varieties of the common Nasturtium, and which at the autumn clearing is thickly strewn with immature seeds. This border is then forked over for neatness, and Nature does the rest. Here are green, sappy seeds consigned direct to a wet, cold bed, to be followed by such results as remarked, and which is, of course, a very common illustration. It is in the attempt to analyse these results that we may safely conclude that not more than 1 per cent. survive the ordeal, and I daresay that under normal conditions of artificial care and treatment the maximum per-centage of plants is obtained. Another conclusion may not be lost sight of—viz., that over and above all the agencies more or less erratic employed by Nature to fulfil her mission man is the chief.

It is not, perhaps, desirable to delve deeply into what may be regarded by some as abstruse questions; space, moreover, would preclude us from going on as we have commenced, although it is little more than the outline of a physiological section of this subject—seeds. Young students can continue it according to opportunity, to the end that rational treatment of these delicate organisms, whether of the costliest Orchid or the commonest vegetable, may be given; for they are equally worthy of an intelligent appreciation of their requirements. Literally and figuratively "as we sow so shall we reap."—AN OLD BOY.

(To be continued.)

LEAFY JUNE.

MAY, the month of hopes and fears, has fled, and we are now well into, what one is inclined to regard, so far as foliage and flowers are concerned, the most glorious month of the twelve. There is so much to please, so much to gladden as the eye roams over a wide stretch of country, and peeps into many a private demesne where free gardening has introduced fine-flowering shrubs. The shrubby Spiræas, gorgeous Rhododendrons, and the thousand things of individual beauty which collectively form a feast satisfying without satiety. Moore's invocation to the month now passed, "Come May with all thy flowers, thy sweetly scented Thorn," pleasantly eulogises a period which, possibly, is accompanied by more anxiety to gardeners than any other, but with the advent of June a feeling prevails that we are well over the danger line.

Very rarely, indeed, in ordinarily favoured localities do we suffer seriously from a relapse after May is out. One such occasion only do I remember when nigh on a score of years ago the night of the 6th of June sadly interfered with our bedding calculations by freezing all stiff, and some two thousand Flower of Spring "Geraniums" were crippled beyond recovery. Respecting May's flowers, its latter days do doubtless shed many riches o'er the scene, but poverty seems always treacherously near at hand, contingent upon sudden falls of temperature, that we hardly feel free to acknowledge the spirit of life and beauty developing with a rush in June till it is dominant through the land.

What a wealth of colour we have now among our forest trees! Oaks alone give such daring tones that the attempt of an artist to reproduce tints almost startling in their vividness would court adverse criticism, even did it not necessitate the labelling of the picture, "This is an Oak." And so with a host of things. There is no more striking contrast to be found than in the pale, plummy, tender green shoots of the Spruce Firs springing from the sombre hued growths of last season. Probably busy workers are too much engrossed this month to do more than give a passing glance when natural forces are rapidly transforming the first flush of beauty in the vegetable kingdom into vigorous growth. There is now more than a struggle for existence amongst the many things so quickly and so disagreeably asserting their right of being.

But few places there are, perhaps, in which during this fast-fleeting month an augmentation of the staff for the period would not be of inestimable service. "Keep the hoes going while weeds are growing" is grand advice; but how few are able to practise it as much as they could wish whilst the "big jobs" are being grappled with! One could easily pick dozens of places where the force of such simple needs are felt; simple they are but mean so much, and the remedy is all but unavailable. For instance, during the whole month of June the normal staff might be wholly employed in hoeing, and there are many indeed in which bedding out, planting out, and other works of vital importance prevent the needful stirring, and so "ill weeds grow apace."

It is a fact, and an unpleasant one, to many a private gardener that his neighbour, the farmer, possesses distinct advantages in the temporary employment of women and boys in the hour of need. As an aid to garden work there is not much to be said for, or even against, the ubiquitous boy, but the advantages conferred in one large garden that I knew by women's labour as an auxiliary during pressure were so great that one could wish this means to an end were more generally favoured, for this labour is both good and cheap.

Very expressive is the name given to this month "praireal," as indeed they all are, in the French revolutionist calendar. The appositeness of "praireal"—the meadow month—must be obvious to even a casual observer, who can hardly fail to catch some of the multitudinous minor notes of beauty now rising from grasses and herbage, so beautiful, so perfect in their modest way. I wonder if our young gardeners, whose attention is claimed by more assertive beauty, ever give a passing recognition to these, the humble and meek of our native flora. Take for example and for observation one square yard of an old pasture during this month, and—well our boys must not be botanists pure and simple, but it is just possible that some knowledge of our native grasses will not only not be superfluous in the days to come, but may be distinctly of advantage to them—to those from whom so much will be expected.

Whether or not the palm for beauty in its most comprehensive aspect is awarded *con amore* to leafy June, as far as gardeners are concerned, it is to them the busiest of busy seasons. Flower gardens that are to be furnished with tender plants may be no longer delayed, and every means to the end of good results quickly attained, and as continuous as possible is the desideratum. Never before, I think, have we been nearer to our ideal of a gay and interesting and generally satisfying method than is now employed by liberal-minded men—gardeners—in planting for summer adorn-

ment, whereby a judicious use of various fashions has deprived anyone of them of that monopoly a primary craze creates. Bright blooms, beautiful foliage, in neat design or bold outline, all combine to charm, to soothe, to satisfy. Yet this is anticipation. There is, to my mind, at present a galaxy of natural beauty that no other month affords—these fresh young days of summer which inspired Southey to apostrophise from the summit of Shooter's Hill the spirit of health borne on "Showery June's dark south-west gale."

—INVICTA.

AMARYLLIS OR HIPPEASTRUMS.

It was my fortune (good or bad?) to have to record before the R.H.S. the history of the garden Pæony from their first advent in our gardens up to comparatively recent times. I had to thank some kind friends, amongst them the aged French nurserymen, M. Charles Verdier and M. Keteleer, and their recollections, for the record of progress from the first, of those interesting plants, the named Pæonies.

In giving a short lecture on Amaryllis at a local Hertfordshire society I essayed to do the same thing for the Hippeastrum, and in the same manner I had to avail myself of the kindly help of living raisers. I had also the advantage of Mr. Veitch's and Mr. Douglas's papers read before the R.H.S., and the careful records of the family given in Dean Herbert's "Amaryllideæ." With Amaryllis, however, it is not the same thing as with Pæonies, for though they can be increased by offsets it is a slow and difficult process, and they rather lend themselves to reproduction from seed. Named sorts, though remaining in collections, do not readily become common garden plants.

But I may be able to tell part of the story of their progress from the earlier species with the help of some of the raisers. The first recorder is the Spofforth Vicar, afterwards Dean Herbert, whose record of the then existing Hippeastrums has been the foundation of all recorders. Mr. Baker's "Amaryllideæ" (1888) brings the family up to that date, and is the most complete botanical account of the order. In Mr. Harry Veitch's and Mr. Douglas's papers we have the most practical, and in the former the most historical, history of the garden forms, and he tells much the same story which I have to relate.

Most interesting letters have reached me recording the respective work done in hybridising by Mr. de Graaf of Leiden, Mr. Heal, Messrs. Veitch's foreman of Amaryllis; and lastly, by one of the earliest raisers, Mr. Baxter, then of Broxbourne, Herts, who about 1868 had several varieties certificated by the R.H.S. I may claim for my own county that Hertfordshire Amaryllis as well as Hertfordshire Roses and fruits have taken a foremost place. Herbert's name of Hippeastrum has been formally adopted in "Genera Plantarum" for the South American species, leaving to the South African *Bella Donna* Linnaeus's original name of Amaryllis.

The two families do not seem to hybridise. So Herbert found. Veitch says, "We have ourselves demonstrated experimentally that they will not cross," and I have not been successful either with these nor with Vallota. If one may take the absence of any special form of deviation in seedlings, the result of seemingly successful crosses, the only distinct characteristics of some such supposed hybrids were more erect flowers. It is curious, as the succeeding family of Amaryllideæ, Cyrtanthus, has given hybrids.

The known wild varieties is larger now than in Herbert's time. He gives fifteen species, Baker's book records thirty-eight. Up to 1867, when Leopoldi and pardinum were introduced by Messrs. Veitch, the kinds bred from were, according to Herbert, Regina (Regium of Herbert), from which sprang the first hybrid, Johnsoni, raised by the Prescott watchmaker of that name; aulicum, and vittatum, the kinds most distinctly, I think, recording its influence amongst all the hybrids; solandriflorum, the kind to which we owe the long slender tubes; and reticulatum and its form striatifolium, the parent of the winter flowers to which Mr. Heal alludes, and of which some old forms of Sweet and Colville existed. To the species bulbulosum, with its varieties, and to fulgidum, equestri-forme and rutilum we probably owe the scarlet of our modern varieties.

Dean Herbert was the first really considerable hybridiser, working from 1824 to 1847. Many crosses figured in the illustrated journals of those and succeeding years. He did not advance much in shape or colour, but he laid the foundation of our present race.

Garraway of Bristol raised, in 1835, from the form of aulicum, figured in the "Botanical Register" of 1826, the variety Acramanni pulcherrimum, and its singular beauty led Van Houtte, De Graaf, and others on the Continent to commence crossing, and in England Messrs. Henderson, Mr. Holford of Westonbirt, Speed of Chatsworth, and amongst others my neighbour Mr. Baxter of Broxbourne.

He writes me:—"My first start with *Amaryllis* growing at Broxbourne was in 1864, with a small bulb of *marginata conspicua*, which I had from a friend. I grew that for about twelve months, then had six bulbs from Ghent (Van Houtte's) which were very poor varieties, and also their petals, but one had very good colours and markings. I thought if I could get it in as good form as *marginata conspicua* it would be a great improvement, so by perseverance I managed to get it into flower by March. I hybridised the fancy-coloured one with *marginata conspicua*, and there came an unexpected variety of colours, from the deepest crimson, such as *Athelt*, without any trace of green in the centre, as in all the other sorts then in cultivation. From the same cross came the other varieties, such as *Olga*, *Madame Tietgens*, *Alexandra*, *Rembrandt*, and *Duke of Edinburgh*. For these I obtained certificates in 1868 and 1869. I showed a good collection in 1868, when Mr. Veitch thought the colours were very good but not in form and substance, so they wanted to exchange *Palan*, which we did for some few years. I think that helped them into the beautiful colours. Of course I could have done more at that time if I had had more space, and could have bought the best formed varieties, but where they are shillings now they were guineas then. Mr. James Williams, on seeing my first batch of seedlings, said it would take me seven years before I could flower them, but it only took me two and a half years. I always rested them in the winter, young as well as old, but I kept them on the move as fast as possible.

Mr. De Graaf tells me his father started in 1830 with varieties of *Johnsoni* and *vittata*. Garraway's *Acramani pulcherrimum* was added to the collection, and with *equestre* and *crocea grandiflora* the work was mostly for colours; but later on, by the use of *equestre*, better forms than the old pipe-shape was obtained, *psittacinum* and *braziliensis* giving also improvements in size and more perfect form. Henderson and Williams had made some march during this period with the winter-flowering *reticulatum*, continuing the old work of Sweet and Colville with *Goweni* and others. *Solandriflorum* had helped on the kinds with bold white edges to the petals.

Mr. Veitch, in his paper, says, "We found, as Dean Herbert had found half a century before, that when we used a particular species, whilst we are able to select several distinct new forms, showing a marked improvement on their progenitors in breadth and substance of segment, size, and symmetry of flowers, many possessed the main features of the species (*Leopoldi*). The finest we called *John Heal*, in recognition of the patience and intelligent perseverance of our coadjutor."

Mr. Heal writes:—"I find we commenced the hybridisation of *Amaryllis* in 1867, when Pearce, our collector, sent us *Leopoldi* and *pardinum* from Peru. The results with *pardinum* were not encouraging, only two, *Brilliant* and *Chelsoni*, did we consider worthy of a name out of a batch between 500 to 600 bulbs; we therefore gave up that species for crossing purposes. With *Leopoldi* we were more successful, and to this species we consider we are indebted to those large well formed flowers of the present day, and those growers who did not make use of the *Leopoldi* blood were left behind in the race for fine bold open flowers. We first crossed *Leopoldi* with the finest Continental and English varieties we could procure, employing it as seed and pollen parent. The first attempt was not a great success, but sufficient to induce us to go on; we therefore started again in 1876 with our best *Leopoldi* crosses, and intercrossing them with *Graviana*, raised by Mr. De Graaf of Leiden, and *Acramani pulcherrima*, raised by Messrs. Garraway & Co. of Bristol, also with pollen we received from Mr. Baxter of Barnet, and the late Rev. T. Staniforth of Storr's Hall, a great amateur and lover of the *Amaryllis*.

"The result of these crosses were most encouraging. We flowered those fine varieties *Lady of the Lake*, *Tennyson*, *John Heal* and others. We were so pleased with the results that we began to look about for fresh blood, in which we were most successful by procuring from Mr. De Graaf's *Empress of India* and a few others. In 1880, when we had such fine varieties to work on as the above, dates a new era for the *Amaryllis*.

"At first *Leopoldi* only gave us two flowers on a scape, but by procuring the Continental varieties with four to six flowers, we were then able to do the same with *Leopoldi* strains. We also crossed with *aulica*, *vittatum*, *equestre*, *solandriflorum*, and other species with very poor results, although we improved the *aulica* strain and the *solandriflorum*, but not sufficiently to make further trials. We were more successful with crossing the *Leopoldi* strain with *reticulata*, which resulted in obtaining a beautiful race of autumn and winter varieties, known as *Autumn Beauty*, *Lady Mayoress*, and few others, which have finer form, flowers, and deeper veins than *reticulata*; those varieties require warmer temperature, so we have not gone on with them. I think this is the history of our *Amaryllis* hybridisation."

My own experience as a raiser I began after a visit to Holland with twelve bulbs of the ordinary then called the seed-shop sorts, and fairly succeeded in flowering most of the twelve the first year. I the next year tried a dozen of the proved named sorts, and my growing with successful culture I bought of De Graaf some eight bulbs of the finest and most distinctly varied of his collection for some £50. One of the Haarlem raisers had a fine collection of the more vigorous old sorts, with much *aulica* in their blood, and I added some three or four bulbs of the best of Messrs. Veitch's finest seedlings of the year. I had also *Brown Beauty* of Reigate, certificated in 1873, and one or two of Baxter's. I am happy to say that during my life I have always found amongst the best raisers a friendly rivalry and a hearty wish for the success of raisers running side by side with each other.

It was some three years after raising my seedlings that I obtained my first success, and my first certificate was obtained in 1889 with *Sea Nymph*; followed in 1892 with *Mars*, a very fine scarlet, and *Silver Queen*, a fine margined kind, and *Firebrand* all in 1892; *Salvator rosea* and *Lightning* in 1893; *Novelty* in 1894. Besides these we won many certificates at the Royal Botanic Society, and took for some years, with occasional defeats, from our old friend and good grower, Mr. Douglas, most of the first prizes for *Hippeastrums* at the R.H.S. and the Crystal Palace Finding, however, that the stock was increasing faster than the sale, we have somewhat ceased hybridising except with a few of the very finest seedlings appearing each year.

My aim has been to differentiate somewhat from other raisers, and instead of seeking mere size and other qualities of the florists to try and gain a new and larger range of colour and the selfs more intense; where margined, their colours more separate and clear, and to maintain the graceful form of the flower, giving it breadth of petal and substance without losing the tubular shape.

Amongst other growers I must not omit Mr. Douglas of Ilford, a well-known name, and Mr. Perkins, the skilful gardener to Lady Hambledon of Henley, whose collection is fine, and grown somewhat differently from our own, and who has already this season shown a fine group at the R.H.S. meeting of February. Taking the R.H.S. list of awards as a fair record of the best varieties, it may interest you to note the succession of the several raisers since the formation of the Floral Committee. Mr. B. S. Williams in 1862; with *Unique* and so on; in 1879 Dr. Masters. Mr. Bull of Chelsea, and Messrs. Henderson, then of St. John's Wood, began in 1863; with *Fire King* and *Brilliant* respectively. Veitch's, with *Virgo* and the spring *Pardina* in 1867, *Leopoldi* in 1869; *Chelsoni*, the first hybrid of these two last, in 1871, whence continuously up to the present date. Garraway of Bristol, with *Cleopatra* and *Hebron* in 1867; Baxter in 1868-1869, with *Alexandra* (named after the popular Princess of Wales), *Olga*, and *Duke of Edinburgh*; 1878, Mr. Little of Twickenham; 1879, Mr. Speed of Chatsworth; 1888, Mr. Kelway; 1889, Mr. Paul; 1892, Lady Hambledon.

As bearing out the difficulty to which I have alluded of propagation, I doubt if you could procure, excepting Dr. Masters, John Heal, and one or two other kinds which produce offsets freely, six plants of any one of this long list of certificated kinds.

FLORISTS ARE ALL AGREED.

The points which the florists are generally agreed upon are that the flowers should be in form triangular, that the petals should be broad, overlapping one another, so that, as in *aulicum*, and the older species, no light may be seen through, and that they show a large face, the crowns also should be joined in the petals. Colour should be clear, if self down to the very base of the throat of the flower, and if white or striped all grey should be eliminated. The flowers of the *Leopoldi* section should be open, but the tubular section need not be so. The form of the *Harrisi Lily* should be rather their type. I could only on looking over some collections shown this spring conclude that the taste which had been fostered was the wrong one, and that the flowers had lost grace and beauty from the desire to show a large open surface. A few men who are ardent florists were gathered round the groups, including our Chairman, and they all, I think, agreed in what I have ventured to say on this point.

CULTURE.

My culture has been fairly successful, and is that adopted by De Graaf, and since by most other (though not universally) growers. The bulbs, dried well off in the autumn, should be shaken out of the soil and pots in which they have been resting in a dry state since September. They should be cleared from all loose skin, dead roots, and in case of any insect pests should be washed round the crowns with a little Gishurst or softsoap. Potting may be done with a few of the very earliest ripened bulbs in December, but generally from the first to the third week in

January. The soil should be half fibrous loam, a quarter leaf soil, and a quarter rotted cow manure, to which should be added about one-third sand when about to use it, for it is well to lay up the soil some two months before using it. Take care to bring the soil into the house to warm before using it, so the roots may be promptly encouraged to at once throw themselves out.

BEST HOUSE FOR AMARYLLIS.

Just a remark or two about the best house for Amaryllis. They seem to do well in any light airy structure; at Lady Hambledon's Mr. Perkins had them on the Peach house shelves, where Strawberries are placed for fruiting. Most of the growers have followed M. De Graaf in placing them in a span-roofed house, running north and south, with a central bed, for flowering the collection, and a bed on either side for the seedling plants. I do not grow on artificial bottom heat, but had on raised beds some 2 feet deep, filled with fresh tan, in which the pots are plunged into the rims. No water is given until the leaves or spikes begin to throw up, showing root action, when a good watering may be given. An occasional syringe of the leaves is good. As the spikes throw up stake them. I grow in a somewhat lower temperature than many growers, though my Hippeastrum house varies in temperature at the two ends, one-half has six pipes, another only four, so that the time of flowering is thereby prolonged. A temperature of about 60° is quite high enough, sinking to 45°, or even lower, at night. On sunny days air may be given, sparingly at first, and more when the foliage is well up. Move the plants when in flower under a shady part, or to the conservatory or a cool house.

After the flowering is past encourage the growth by continuous watering and some gentle stimulant until September, then they may be gradually dried off, and put away—pots, soil, and all—on to a dry frost-proof shelf, or under dry drip-proof stages, being after this stage kept without water until the time of repotting comes.

SEEDING.

All flowers should be cross-fertilised, either with the other flower on the spike or with good other sorts in flower at the same time. Remove the anthers from the plants to be seeded, apply the pollen, and a certain number of seed pods usually result. The seed ripening, in some six weeks' time, I prefer to sow at once, and to keep the seedlings growing as evergreens for the next two years. They may be propagated by the removal and repotting in small pots of the side offsets. These are not numerous, and only worth securing in the case of very choice kinds. Seed is easily secured, and the seedlings usually produce a proportion of good kinds. If hybridised the chances of stronger progeny is better, care being taken to have good vigorous seed-bearers. As to whether they are worth the culture (it is simple) I think, looking at the beautiful flowers we have, it is. They are very showy, bloom at a time of year we welcome all flowers, are useful for home decoration as plants or cut flowers, and have at least an interesting history.—(Read by MR. GEO. PAUL at a meeting of the Horticultural Club.)

ACROSS THE CHANNEL.

ANYONE interested in gardening, who may happen to visit Paris in the month of April, should not fail to have a run through the Bois de Boulogne, for I think its aspect is then more beautiful and varied than at any other period. A very delightful way of seeing the "Bois" is to take a "fiacre," and go for an hour or two's drive along its fine avenues of Chestnuts and Planes, and through the woods of Poplars, Limes, Oaks, and Beeches then just budding into new growth. A further charm is added by the wild plants in flower—Polyanthus, Lychnis, and Periwinkle.

The lakes and the several small, well-wooded islands form an attractive feature of this park. Their banks are clothed with the Weeping Willow, Ash, and Beech, and many specimens in flower of Magnolia conspicua, Forsythias, Prunus, Ribes, and Berberis. The islands are chiefly planted with evergreen trees and shrubs interspersed with Magnolias, Acers, and the deciduous Cypress. If we follow the road by the side of the lake in the direction of Longchamps racecourse, we shall pass several effective waterfalls pursuing their course between rocks clad with Ivy or other creepers, and surrounded and shaded by the Birch, Ash, Pine, and Willow.

Bearing to the right we presently emerge from the wood to find a fine panorama of sylvan scenery stretched before us. Nestling on the wooded slopes of the distant hills, Sèvres and Saint Cloud may be distinguished, while to the right of these Mont Valérien stands out clearly above the village of Auteuil and the Seine valley. On our return journey we pass "La Grande Cascade," where the water falls from a height of perhaps 50 feet over rocks, clothed with luxuriant vegetation.

The "Jardin d'Acclimatation"—the Regent's Park of Paris—is

situated in the Bois de Boulogne. It is interesting to the lover of horticulture and zoology alike, and a short time may be very pleasantly spent there. A novel and enjoyable way to reach it is to take the miniature pony tram from the entrance gate of the park. The journey, which occupies about ten minutes, takes one right through the dells and glades of the "Bois." Inside the Jardin d'Acclimatation the grounds are of a different nature. The flower beds are bright with Wallflowers, Aubrietias, Polyanthus, Myosotis, Tulips, and Hyacinths. These, together with the various flowering shrubs of Prunus, Forsythias, and Pyrus contrasting pleasingly with the many tints of foliage in the background.

As one enters the gardens, on the right is a block of houses devoted to the culture of Palms. These contain quantities of fine healthy looking plants of Phoenix reclinata, Latania borbonica, Kentia Belmoreana, Areca lutescens, Rhaphis flabelliformis, Geonoma gracilis, Cocos Weddelliana, and others.

But the chief horticultural feature of the Jardin d'Acclimatation is the large "Jardin d'Hiver," situated to the left of the main entrance. It may be described as an oblong building, about 50 yards long, by 20 yards wide, and 30 yards high. It has a curiously shaped roof, consisting of a series of semicircular ridges. Adjoining one side of the house, and running the full length of it, is a conservatory. On the opposite side there are several small span-roofed stoves, all opening into the larger house. The centre beds of the conservatory are planted with fine pyramidal shaped specimens of Camellia reticulata, C. Spoffortiana, and C. Kilvingtonia; graceful Grevilleas, sweetly scented Indian Rhododendrons, and Acacias adorn the sides. The groundwork of Selaginella is relieved by various flowering plants in pots plunged in the bed, the distinct blue and rose-coloured Cineraria being especially striking.

The stoves contain collections of ornamental foliage plants, Orchids and Bromeliads. The interior of the large glass house into which the others mentioned converge is very tastefully laid out. A broad raised walk skirts the outer edge of it, and below smaller walks with graceful curves run alongside, or sometimes cross the pretty winding stream in the centre. Clumps of Bamboos and large Strelitzias are planted at intervals in the side beds, the spaces between being filled with Begonias, Aspidistras and Tradescantias. The water is flanked on each side by a beautiful green carpet of Lycopodium, dotted here and there with Primula obconica, Cinerarias, Genistas, Clivias, Azileas, Begonias, and other plants in flower.

Palms succeed here admirably. The specimens of Seaforthia elegans, Areca sapida, Sabal umbraculifera, Cocos australis, C. Romanzoffiana, and Rhaphis flabelliformis are really fine. Other noticeable plants growing luxuriantly are Acanthus lusitanicus, Ruscus androgynus, Caladium esculentum, Oreopanax dactylifolium, and Hebeclinium ianthinum.

The rock garden and dell of Tree Ferns at one end of the house form a pretty feature. The handsome clumps of Dicksonias, Cyatheas, and Alsophilas give quite a tropical aspect to this corner. The rockwork is almost hidden beneath the growths of Begonias, Panicum, and small Ferns.

Close by a rustic bridge which crosses the stream is a splendid mass of Asparagus plumosus growing in great profusion. In a large corridor leading from this end of the Jardin d'Hiver there are some remarkably fine specimens of Cocos plumosa growing in tubs, and certainly not less than 40 feet high.—H. T.

NON-PRODUCTIVE STRAWBERRY PLANTS.

WHEN on a recent visit to Tamworth my attention was drawn to a large quarter of President Strawberry plants in a most vigorous state of health, but not a single truss of flower was to be seen; whilst several other varieties, including Royal Sovereign, growing close by under the same treatment were in abundant bloom. The owner contemplated preserving them (the plants in question) for another season in the hope that they might prove productive of fruit, but on my recommendation purposes to chop them up at once and plant the space with Violas for sale when established.

So far as I am cognisant the real cause of this abnormal condition so frequently observed amongst Strawberry plants remains a mystery, though more than one theory has been hazarded by growers and physiologists towards a solution of the problem.

Apparently this lack of fructification is a constitutional defect possessed by certain varieties, and which is augmented by over-feeding whilst in the growing state. The matter is worthy of the serious attention of the scientist, though the most drastic measure would be to destroy such plants at once.

Cows appear to be very fond of the foliage of Strawberries, and I recommended my Tamworth friend to fodder his own cows with that of the blind plants, jocosely remarking that thereby the cow's laboratory might produce him "Strawberries and cream" *ad libitum* without further trouble.—QUERIST.

WEATHER IN LONDON.—The metropolis has been thoroughly warmed during the past seven days. On Thursday, Friday, and Saturday of last week the sun shone with great brilliancy and considerable power. Sunday afternoon brought a thunderstorm with rain, but the air was not much cooler until Monday, when it was dull the whole of the day, a little rain falling at intervals. Tuesday was cold, and brought several sharp showers; while Wednesday proved dull and wet.

— MR. MARTIN H. FOQUETT SUTTON.—At a dinner given at Reading recently by Messrs. Sutton & Sons it was announced on behalf of the firm that, in addition to the day's pay on June 22nd, a sum representing an extra week's wages would be presented to everyone in their employ, in honour of the Diamond Jubilee of the firm's patron, her Majesty the Queen. The dinner was given to several hundreds of the firm's employes at Reading on the occasion of Mr. Martin H. Foquett Sutton becoming a partner. His health was proposed by his grandfather, Mr. Martin Hope Sutton, now in his eighty-third year, who founded the firm more than sixty years ago. The evening was one of the many pleasant ones that have been passed by the employes of this firm.

— STREPTOCARPUS.—The strain of these beautiful flowers, originally derived from Messrs. Veitch & Sons, which Mr. Salter has at Woodhatch, is particularly rich in deep colours. The reds and blues are almost intense, and clearly indicate that we shall see in them in a few years some striking colouration. The strain so far is of the floribundus type, but here and there an infusion of the cluster or truss flowering style of *gratus* seems evident. Mr. Salter has been working to obtain yellow hues, but time alone will show what will result. It is very evident, judging by what firms like Messrs. Veitch & Sons and Messrs. Sutton & Sons have done and are doing for the *Streptocarpus*, and such private growers as Mr. Salter, that these plants have before them a great future.—A. D.

— ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—One of the most decided efforts that is being made by any horticultural society in celebration of the Diamond Jubilee, is that of the Royal Caledonian Horticultural Society. At its autumn show, to be held on September 8th and 9th, besides the ordinary classes, there will be some termed Victoria Diamond Jubilee prizes, in four classes, one each for fruit, plants, cut flowers, and vegetables, of which the first and last are open to gardeners and amateurs, and the second and third to all. The first is for the best and most tastefully decorated table of dessert fruit, 10 feet long by 4 feet 6 inches wide. There are three prizes of 20, 12, and 7 guineas respectively, as well as medals. The plant class, for a group, takes similar generous prizes, while the cut flower is for a table 15 feet long by 5 feet wide, the prizes being 10, 7, and 4 guineas, again with medals. For vegetables the prizes are as in the cut flower class, and the table space allotted is 12 feet long by 5 feet wide. For full particulars write to the Assistant Secretary, Royal Caledonian Horticultural Society, 18, Waverley Market, Edinburgh.

— LUPINUS ARBOREUS.—This is one of several beautiful semi-shrubby leguminous plants which are well adapted either for an herbaceous border or the front row of a shrubbery. Commonly known as the "Tree Lupine," it forms, with a little stopping when young, a dense shrub 2½ to 3 feet in height, with soft fleshy stems. The compound leaves are usually composed of nine or ten linear-lanceolate leaflets, which almost form a circle. They are thickly covered, particularly on the under surface, with soft silvery hairs, which add greatly to their beauty. The flowers are produced during May, June, and July on upright racemes, which terminate growths of the current season. The racemes are 6 to 8 inches in length, and are composed of yellow flowers grouped usually seven together in semi-whorls three-quarters of an inch apart. It is a Californian plant. Although perfectly hardy in ordinary winters, a spell of severe frost sometimes proves too much for it, consequently it is necessary to propagate a few plants either from seeds or cuttings each autumn, and winter them in a cold frame if its safety is to be insured.—D. K.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral Meeting of the Royal Horticultural Society will be held on Tuesday, June 15th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "The Physiology of Plants" will be given at three o'clock, by Prof. S. H. Vines, F.R.S.

— NOTTINGHAMSHIRE HORTICULTURAL SOCIETY.—The Arboretum, Nottingham, will be *en fête* on July 14th and 15th, when the above Society holds its annual show. This year the proceeds are to be devoted to the funds of the local hospitals, and it is to be hoped that with such an object in view the show will be well patronised. The schedule contains forty-five classes, in which prizes are offered. The Hon. Secretary is Mr. J. M. Stewart, 16, Market Street, Nottingham.

— NEW LUNGS FOR LONDON.—At the monthly meeting of the Metropolitan Public Gardens Association plans were submitted and approved for the laying out of Albion Square, Dalston, and the Paragon, New Kent Road, and seats were granted for Kennington Green; West Hill, Wandsworth; the Oval, City Road; and Wendell Park, Starch Green. It was also decided to assist in the promotion of a scheme for utilising as a recreation ground a cleared area in Morton Road, Islington.

— ROYAL METEOROLOGICAL SOCIETY.—At the next ordinary meeting of the Society, to be held in the rooms of the Royal Astronomical Society, in the Quadrangle of Burlington House, Piccadilly, W., on Wednesday, the 16th inst., at 4.30 P.M., the following papers will be read:—"The Non-Instrumental Meteorology of London, 1713-1896," by R. C. Mossman, F.R.S.E., F.R.Met.Soc. "Hailstorm in the South-West of London, April 27th, 1897," by Charles Harding, F.R.Met.Soc. Tea and coffee will be served from 4 to 4.30 P.M.

— KENT COUNTY CHRYSANTHEMUM SOCIETY.—The schedule of the Show of this Society, which will be held at the Rink, Blackheath, on November 3rd and 4th, is to hand. It enumerates forty-seven classes, divided between sections that are open to all, for gardeners, for amateurs, and for ladies. Capital prizes are offered, and this year's show will, it is hoped, maintain the character for high quality that the Society has held for some years. The Hon. Secretary is Mr. F. Fox, The Cedars Gardens, Lee, S.E., who will furnish all particulars on application.

— DAPHNE CNEORUM.—Among low trailing shrubs suitable for the rock garden there is none more beautiful than the alpine *Daphne Cneorum*, which is found on the calcareous soil in the Jura and southern Alps as well as in Hungary and Transylvania. In its home it is often called the Pearl of the Mountains, and its close clusters of delicately scented rose-coloured flowers are now, says the "Garden and Forest," at their best. It is an old plant in gardens, and we call attention to it every year, but its beauty cannot be too highly praised. The roots are fine and thread-like, which shows that they like to wander in deep light soil.

— CARNATIONS AT TEDDINGTON.—Mr. G. May, who did so much to popularise that fine crimson Carnation *Uriah Pike*, grows it for cutting from in immense quantities, and in splendid condition. Visitors privileged to look through the nursery see house after house full of strong plants; literally they are in thousands, all sturdy, healthy, and as even over the tops as if mown, yet carrying flower buds in marvellous quantity, and such fine, rich-coloured, and sweetly perfumed flowers also. It is only needful to see these plants to understand what a good grower and free bloomer the variety is. The next one most highly favoured seems to be the rich pink-flowered *Duchess of Fife*, a great beauty on Miss Jolliffe. This is also a fine robust form, and the pretty yet good sized flowers are in great demand.—A.

— VIBURNUM TOMENTOSUM VAR. PLICATUM.—One of the choicest of our late spring flowering shrubs is the one under notice. In the sterile form the heads of flowers resemble those of our common Snowball Tree "*Viburnum Opulus* var. sterile," but they are much larger, whiter, and more freely produced. The heads of flowers are 3½ to 4 inches in diameter, composed of blossoms 1½ inch across, thickly crowded together. The leaves are acutely ovate, 4 inches in length by 2 inches in width, hairy on the under surface, almost glabrous on the upper, deep glossy green, with deep serrated margins. Good soil should be given, as it is a gross feeder, and long strong shoots should be encouraged, as the better the growths made during the one year, the better the following year's display of bloom. It should be grown from cuttings. For the first two winters young plants should be given a protected place, as when young they are sometimes damaged by hard frosts.—D.

— WELCOME RAIN.—Mr. J. Udale, Droitwich, writes, "Welcome rain came on June 1st and 2nd with a higher temperature, and vegetation is now making better progress. Aphis was making its appearance very plainly upon many Plum trees, but the trees will now outgrow its attacks."

— RAINFALL AT ABBOTS LEIGH, SUSSEX.—The total rainfall at Abbots Leigh, Haywards Heath, Sussex, for May was 1.16 inch, being 0.29 inch below the average. The heaviest fall was 0.39 on the 30th. Rain fell on eleven days. The maximum temperature was 73° on the 17th, 18th, and 30th. The minimum 30° on the 13th. Mean maximum, 62.27; mean minimum, 41.30°; mean temperature, 51.78°—1.93° below the average.—R. I.

— MAY WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M., 50.83°. Wet bulb, 46.04°. Mean maximum, 56.93; mean minimum, 39.55. Highest, 67.0° on the 31st; lowest, 31.8° on the 13th. Mean of maxima and minima, 48.24°. Mean radiation temperature on the grass, 36.01°. Lowest, 26.4° on the 13th. Rainfall, 1.03 inch. Number of rainy days, eight. Greatest amount on one day, 0.37 inch on the 29th.—W. E. LOVELL, *Observer, York Road, Driffeld.*

— MAY WEATHER AT DOWLAIS.—Rainfall, 1.87 inch. Maximum, 0.44 inch on the 29th. Number of days on which rain fell, thirteen. Thermometer: Highest reading, 86° on the 24th; minimum, 24° on the 12th. The temperature was below 33° on eight nights. Mean maximum for the month, 62°; mean minimum, 36°. The wind was in the S.W. and W. on nineteen days, and in the N. and N.E. on eleven days, and until the 22nd was very strong and bitterly cold the whole of the time, with regular blinding storms of snow on the 12th. There were five sunless days.—WM. MABBOTT, *Dowlais, S. Wales.*

— PYRUS MAULEI.—This is one of the most showy of the early spring-flowering shrubs, and being a native of Japan (whence the late Mr. Maule of Bristol imported it) is perfectly hardy. We have several plants in the pleasure grounds growing naturally. They are 4 or 5 feet in diameter, and being wreathed with thousands of blooms for several weeks in succession have been much admired. This variety has the advantage of fruiting freely in the autumn, which gives it a very handsome appearance. It is easily propagated, either from seeds or divisions.—S, *Yorks.*

— PRESENTATION TO MR. INGLIS OF HOWICK.—We receive on Wednesday, when preparing for press, a lengthy report of an interesting meeting, but all we can do is to give the purport of it—namely, that Mr. D. Inglis, who for the last twenty-two years has acted in the capacity of head gardener to Earl Grey of Howick, and who during that time has made himself extremely popular, not only at Howick, but in the district generally, was made the recipient of a handsome inlaid rose-wood cabinet by the parishioners of Howick and other friends on his leaving the district to take up the duties of head gardener to his Grace the Duke of Buccleuch at Drumlanrig Castle. A silver plate bearing the following inscription has been let into the cabinet:—"Presented to Mr. Inglis as a token of esteem and regard by parishioners and friends on leaving Howick. May, 1897."

— ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—The last monthly meeting of the above Association was held at Sandown on Saturday last, when a very enthusiastic meeting was presided over by Dr. J. Groves, B.A., J.P. Mr. Alfred Outram's admirable paper on "The Progress of Horticulture in America," read by Mr. C. Orchard, afforded much scope for discussion, and finally it was agreed that Englishmen had played an important part in the development and progress of horticulture in the United States. The Chairman gave a very interesting account of his many visits to America; whilst Mr. C. Orchard spoke of his experiences when gardener to an American family of note. The platform and table contained horticultural exhibits. Mr. Jos. Perkins, gardener to G. W. Drabble, Esq., Los Altos, Sandown, staged Crotons, Palms, and Dracænas; Mr. James Mackett, Bembridge, a dish of Sutton's Ringleader Potatoes; Mr. Hy. Love, Sandown, blooms of Duchess of York and Lago Maggiore Chrysanthemums, the former from a cut-down plant last November, and the latter from an autumn-rooted cutting; and Mr. C. Orchard staged blooms of Duchess of York Pink, a sport from Mrs. Sinkins, which was pure white with crimson base. A unanimous vote of thanks was accorded the writer and reader of the paper, and also to those who had forwarded exhibits. Mr. S. Gibbs, C.C., who is an enthusiastic educationalist, spoke on the importance of horticulture in the Garden Isle, and of its development during the existence of the County Council, and the scope that still exists for further development. Several new members were elected.

— FLOWERS IN NEW YORK.—The prices of flowers were, perhaps, never so low in this city as they were one week in May, when Carnations brought as little as 1 dol. a thousand, and a regular rate for Roses was 5 dols. a thousand. Indeed, many of the highest-grade flowers could not be disposed of at any price. Besides the close of the social season, another reason for the slow sales, says an American journal, is the abundant use of sprays of Lilac and other early spring flowers, both wild and cultivated, and flowering branches of trees and native shrubs for church and other decorations. These flowers are for sale by the armful on the street corners, or they can be had for the picking almost anywhere in the suburbs.

— A DOUBLE WHITE ANEMONE CORONARIA.—Notwithstanding the number of white flowers which we now have to choose from, any new one is welcome if it be of distinct merit. For this reason we anticipate that the new double white Anemone, of Messrs. E. H. Krelage & Sons, Haarlem, Holland, will be well received. The variety is named The Bride, flore pleno, having originated from the well-known single variety of the same name in the nursery of the above named firm. The flowers are of good size and substance, travelling well through the post. The colour is silvery white tinged with green when the flowers are young, this giving place to cream as age is gained. We understand that Messrs. Krelage & Sons will offer bulbs this autumn.

— TOMATO HEPPER'S GOLIATH.—This is an old variety; indeed, having regard to the average existence of varieties, it is a very old one. Mr. Hepper raised it when gardener at The Elms, Acton, some twenty years since at least. It is of the Trophy type. I saw it growing recently in a low lean-to house at Woodhatch, Reigate. Mr. Salter mentioned that he found it there when he went to Woodhatch, and he has grown it ever since. Howsoever old, it is there at least a wonderfully prolific variety, cropping enormously. The plants are throughout full of racemes of flowers of immense size, and the ripe fruits are large, very solid, rich in colour, and handsome. No doubt it has been improved by yearly selection from the best fruits, but no new variety could possibly excel this old one in productiveness. The plants are growing in a long wooden trough 16 inches wide and 8 inches deep, and are planted at 15 inches apart. In spite of this restriction of root area they promise to go on fruiting for several months.

— WAKEFIELD PAXTON SOCIETY.—Programme of meetings for the second quarter, session 1897:—Meetings are held at the Paxton Room, Woolpacks Hotel, Corn Market, Westgate, each Saturday evening, at 8 o'clock prompt. June 12th, Wild Flower Exhibition, essay by Mr. G. Bott; June 19th, "Wild Birds: Useful and Injurious," Mr. C. F. Archibald, Yorkshire College; June 26th, "A Talk about Hardy Flowers" (specimens of alpine or herbaceous plants may be brought for naming), Mr. John Wood, Kirkstall; July 3rd, "Heating and Ventilation," Mr. J. Thomas; July 10th, The Pelargonium Exhibition, essay by Mr. W. E. Corden; July 17th, "Room and Window Decorations," Mr. L. Twigge; July 24th, The Rose Exhibition, essay by Mr. T. Wilson; July 31st, The Carnation and Picotee Exhibition, essay by Mr. Allison; Aug. 7th, Afternoon Visit to Woolley Park; Aug. 14th, "Our Apple Trees," Mr. J. L. Pickard, Leeds; Aug. 21st, "The Begonia" (with specimens), Mr. W. H. Vere; Aug. 28th, "The Gladiolus," Mr. W. Hudson.

— ANOTHER PRESENTATION TO MR. DAVID THOMSON.—We have previously recorded the presentation of a marble timepiece to Mr. Thomson and silver plate to his daughter by the working staff of Drumlanrig Gardens. As we are going to press we are apprised of other presentations, to which we can only very briefly refer. Last week the Rev. David Black headed a deputation, and in well-chosen expressions of the appreciation of the high character of Mr. Thomson, his devotion to and punctuality in duty, his modesty of demeanour, and natural kindness, asked his acceptance of an ornate clock, also a binocular glass, and of Miss Thomson the acceptance of a gold bracelet, set with brilliants. The clock, with four gongs and eight bells, bears the inscription, "Presented by some friends and acquaintances in Nithsdale to Mr. David Thomson, Drumlanrig Gardens, in token of their esteem for his personal character and professional eminence, 1897." In accepting the gifts Mr. Thomson referred to the sore wrench, enforced by time, of leaving his beautiful home and the superintendence of the premier gardens of Scotland, as well as of valued friends and fellow servants, with not one of whom he had ever had the shadow of an unpleasant word, concluding with what Naomi said when parting with her daughter-in-law—"May the Lord deal kindly with you as ye have dealt with mine and with me." Mr. Thomson will, we understand, reside in future at Eskbank, near Dalkeith.

HER MAJESTY'S DIAMOND JUBILEE AND THE "JOURNAL OF HORTICULTURE."

IN celebration of the great historical event, now approaching, it has been decided to publish an enlarged issue of this *Journal* on the 24th inst. It will be devoted to a fuller description of the gardens of the Queen than has yet appeared, together with a general survey of horticulture, in the form of interesting reminiscences during a period of sixty years, by the Rev. H. H. D'Ombra.

For the purpose of this issue her Majesty has been graciously pleased to grant to the Editor unrestricted permission to illustrate and describe the Queen's beautiful private gardens at Frogmore House, and to enumerate the unequalled collection of Royal memorial trees therein, the first time, we believe, that this privilege has been accorded.

In addition, the past history and the present condition of the gardens at Windsor Castle, the slopes, and Adelaide Cottage garden will receive adequate attention, while descriptions will be given of the great supply gardens at Frogmore, Royal Lodge gardens, the noble Vine at Cumberland Lodge, the Royal pavilion gardens at Virginia Water and Aldershot, the Hampton Court Vine and private gardens—all these being under the direction of her Majesty's head gardener, Mr. Owen Thomas, F.R.H.S. At the same time will appear illustrated descriptions of the Royal gardens, Buckingham Palace, Osborne, and Balmoral; also, by direct sanction, a portrait of her Majesty.

We have reason to believe that such an issue, for which (though of necessity costly) no extra charge will be made, will be acceptable to our readers as a memento of a happy and unique event. We make this notification for two reasons.

1, The possibility of the matter and illustrations occupying the whole space at disposal, and therefore that reports of shows and even answers to correspondents may have to stand over.

2, To give notice that the issue will have to be prepared a week in advance, and therefore those readers who desire extra copies for preservation or presentation to friends should order them *at once*, either through local booksellers, railway bookstalls, or direct from the office, 171, Fleet Street, E.C., to prevent disappointment, which we desire to avert.

We undertake to give more than value for money, and fear that unless orders for extra copies are given before the 17th inst. many applicants will be too late.

STYRAX OBASIA.

THIS is known to few except botanists and those who have made a special study of trees and shrubs. It is said to be a native of the province Senano in the Island of Nippon. The leaves when of full size are 8 to 10 inches in diameter, nearly round in outline, frequently irregularly and deeply serrated at the apical margin, of a light soft green, much like the Catalpa. The tree is bushy in habit, producing its pure white flowers in racemes 6 to 8 inches long, the petals somewhat narrow and pointed, as shown in the illustration. The leaves depicted there, however, are those found at the base of the racemes on the flowering branches, and are not nearly so large as the mature leaves lower down the branches. It has proved quite hardy in a southern garden, where it stands on a slope moderately sheltered by hedges.

AN ESCAPE FROM BABYLON.

MR. AND MRS. ANCIENT BRITON (to be hereafter referred to as A. B.), and two others being tired of town life for the time being, decided upon an escape into the country. Though fond of gardening, and more or less associated with it, they had had enough, again for the time being, especially as some of them, at least, had been in one way or another officiating at the Temple Show; in what precise way it is not necessary to particularise; they only liked to feel they *had* been "officiating," though if the matter were probed to the bottom it might possibly have resolved itself into the fact that they had simply been there.

Well, it was something to have been drawn into the vortex of the fashionables, and almost overwhelmed with the wondrous beauty of the Orchids; the pure and ruddy charms of the Roses; the brilliancy of the Begonias; the chaste and cheering coloration of the Caladiums; the great glistening sea of Gloxinias; the spick and span and sparkling Streptocarpuses; the toothsome-looking, but noli-me-tangere Nectarines, and other fruits; the mouth-watering Mushrooms; the potfuls of perky Peas, as if asking to be picked; and Potatoes pressing their noses against the windows of the boxes in which they are confined, as if to say, "We are not to be sneezed at;" yes, it was something to have been there, and

bewildered—something to have had enough of everything—so much indeed as to make us wish, if not cry, for a change.

"What a glorious art is gardening," remarked Mr. A. B. to the Scribe; "what would the world be without it, I wonder!" "Not the bright and beautiful world it is, certainly," was the obvious reply; "but all the same, don't you feel these shows a little—well, a little humiliating?" The response came hesitatingly, but as it proved, understandably, "N—no. I can't say I exactly feel that; on the contrary I feel rather proud of them—proud to think that we," a very slight emphasis on the "we,"—"can do so much." That was a natural reflection on the part of Mr. A. B., who happened to be in the honour's list, but his friend, who had got nothing, was the reverse of elated—in fact the conceit had been taken out of him, as competition *does* take it out of not a few, who when leaving home are "sure of a prize if the judges know their business." Poor "S." felt that he could do nothing like what others had done, and the show seemed to have at the moment lost its charms for him, and he seemed (and felt) anxious to get out of it.

To get quite away from it was, however, another thing; but happily the fates favoured, for Mr. A. B., "full" of his glorious theme, sententiously remarked that the "world without gardening would be a forest." Lucky word, a "forest." The theme was changed in a breath, the exit clear. "Ah, my dear A. B., do you not remember how happy the late Lord Beaconsfield was in his own 'green retreats,' in which he said, however attractive some other things were for a time, they in time wearied, but that 'sylvan scenery never palled.' You must know that Mr. A. B. is perhaps a 'bit of a Tory,' though it is hard to tell. Suffice that his attention was caught, and that gardens were for the moment left behind. It was clear enough he wanted to sing, but he couldn't quite remember the lines:—

"In the days of old when forest and glade
To the hunter's horn were free,
And the merry men rode through brake and glen,
To meet at the trysting tree."

"If you see an advantage seize it, and seize it promptly," is a maxim worth remembering; and so it came to pass that a suggestion was made for a day in a forest. "With all my heart," was the response of the ardent gardener, "but what forest?" The bow was drawn at a venture. "Have you been to Epping?" A good shot, because it brought down a "No, never." Then, aside, to Mrs. A. B., "What do you say to a day in Epping Forest?" Promptly came the reply, "Delighted!" "And you, Mrs. S.?" "Oh, charmed!" Libel the ladies as you will on their loquacity, but please recognise the force of their laconisms in settling in a moment what a pair of gardeners might prose over for half a night.

It so happened that none of us had been to Epping, and the combined knowledge of the group was not equal to a solution of the problem as to how to get there, or rather, as to the station to which to book for the best. The Forest was thought to be in Essex, and therefore most likely to be reached from the capacious city terminus of the Great Eastern Railway in Liverpool Street. But the Forest station was the difficulty. We were told that Woodford and Cheshunt, Buckhurst Hill and Theydon, Waltham Cross and Epping were on the borders. But as borders in gardens vary from 2 to 10 feet or more, it was thought they might vary in Nature to as many miles, and so a decision could not be arrived at. "What stupid we must be," observed one of the four, after a long pause; "has not Mr. George Paul a place in the Forest?" The problem was solved, and forthwith went the following letter.

"Dear Mr. Paul,—Mr. and Mrs. A. B., the former of whom you will know by sight, and the latter is worth knowing, are with self and Mrs. S. consumed with a desire to escape from Babylon with all its crush and hurly-burly—the hoisting of deals and the noise of hammers in fixing up tiers of Jubilee seats from the ground to the house tops. We want to get away from this, if only for a little while, and spend a quiet day in Epping Forest; but as our geographical ignorance is colossal, the favour of your advice as to the arrival station and route will be gratefully appreciated." Quickly came the following reply, "Dear Mr. Scribe,—Don't come to any of the stations you name, but book to Chingford; trains from Liverpool Street every half hour; comfortable barouches to hold four await all trains. I am staying at my cottage at High Beech for a fortnight; drive there—only two or three miles. I will show you the pretty features round the Beeches, and point out botanical treasures, going with you as far as what we call the Drosera field, where we find *Lycopodium inundatum* (Marsh Club Moss), and then I could direct your driver to Epping and Theydon

and back again to Chingford." A stroke of luck surely, and Liverpool Street at eleven o'clock was fixed as the place and time of meeting.

[But what a morning! The thunder, as it seemed, shaking the world, the rain falling in torrents. What is to be done under such circumstances? The answer is plain. When an appointment is made keep it, no matter what the weather may be. So evidently thought the Britons, and the meeting took place to the moment. To go or not to go further then became the question. "We had better go," said one. "Hear, hear," said the other; "better start in the rain and finish in the sun, than start in the sun and finish in the rain." And so the matter was settled. A race to the booking

stand, and be happy in either; but I can't be happy in a second," said he. But why? "Because," he went on, "it makes me look and feel too conceited for a third yet not able to raise the wind for a first, and I don't like it." This genuine man, without guile, has long since gone, without the experience of travelling third from Epping Forest with nineteen or twenty others in a compartment made for ten, or he would gladly have given a few more pence for a little more room wherever he might find it.

But we are at Chingford, and the rain has practically ceased. "Now, Mr. A. B., you are a judge of horses, choose a good one"—for there was plenty of choice. He suggested a pair. "A pair; no, there are no pairs here, and besides there is not much more

FIG. 97.—STYRAX OBASSIA.

office, and the best man won. "Four second returns Chingford." No, it was not particularly extravagant—twenty-two miles for 1s. 4d. a head, or body; but it calls to mind an episode.

It is not the old chestnut of the Bishop travelling "third" because there was not a fourth class, though that may be true, as something else is most certainly. Some years ago, more than one likes to count, a band of horticulturists, rich and poor, went on a fruit-exploring expedition into Kent. At Victoria Station some of the latter, not liking to "look" their worst, boldly asked for "second returns." The rich ones followed suit—a delicate act, such as is only seen from thorough gentlemen. They would have no distinction in classes then, and abandoned the usual "firsts." Only one of the party grumbled at the "second" class, and a good man too—the late celebrated market gardener of Chiswick, Mr. Frank Dancer. "First I can understand and third I can under-

than a quarter of a ton of us, and a good animal won't mind that." The best was chosen, and trotted along with ease, especially a little down hill. A somewhat similar party of four once took tickets from Wallington to the next station, Waddon, near Croydon. While waiting for the train the time was passed in weighing. Not being midgets the results were watched by others, and especially by a dainty little porter. "What class, sir?" as the train was coming up. "Oh! third, of course." "All of you?" "Yes, certainly." The scorn of the man was a treat to see, as he shouted, "Of all the cheek! Here is a party weighing twelve stone over a quarter of a ton, all going for sixpence (1½d. each), and then folk howl about railway rates." He scored that time, and was happy amid the hilarity.

When the great Forest of Epping was secured by the Corporation of London as a breathing ground for the people some twenty

years ago, it was opened by the Queen. A triumphal arch was erected over the station, and it remains to this day, minus, of course, the trappings. We proceed to the Forest, close by, between an avenue of young Limes, passing an imposing hotel, and Queen Elizabeth's hunting lodge. On the right are stately trees, standing at sufficient distances for development on the green sward; on the left, an open, treeless, undulated plain—golf links of 300 acres. The excellent road gradually rises through a cold, damp, clayey portion of the Forest, in which the few trees are stunted; but as we ascend, the land and trees improve, and we are soon in almost an impenetrable forest of healthy Beeches. By sundry twists and turns the higher level is reached, and we are suddenly overlooking glowing masses of Rhododendrons, amidst which an ancient cottage seems to nestle. A charming spot is this—the High Beech Nursery of Messrs. Paul & Son, Cheshunt. It is an opening of some twelve or fourteen acres in the middle of the Forest, surrounded at a little distance on all sides by a lofty wall of Beeches. Mr. William Paul, we were told, has a still larger extent somewhere not far distant. These nurseries were only retained after a keen legal contest.

When the Forest was acquired for the public, residents who had settled on it could only retain the land they occupied by proving a certain number of years' possession, often no easy matter. When high authorities personally inspected the enclosures in dispute they called at a fortunate time. In the grounds attached to the cottage mentioned is, among other features, an avenue of Rhododendrons—splendid standards, with huge heads covered with noble trusses rising from a base of young flowering shrubs and hardy Azaleas. When the inspectors looked down this flowery avenue, as we did, they appear to have been enchanted. They could not advise its being given back to Nature, but yet had to consider the question of public interest, and the matter was settled on sensible lines. They obtained for the public access to the nursery (except the small cottage enclosure), and in return recognised the proprietary rights of the present owners. This beautiful nursery is, then, open to the public, far more benefit no doubt resulting to the proprietors by the advertisement than loss by the possible plucking of a flower.

It is fair to say that Mr. George Paul did not press us to inspect his treasures, for he is a connoisseur as well as a nurseryman; but offered us a warm cottage welcome, and was ready to show us the Forest, as a greater novelty to us than his "cultures;" but Mr. A. B. went straight for the great masses of colour, and the rest had to follow. Rhododendrons are at home at High Beech, in all sizes and all colours, from the smooth purity of Mrs. John Clutton to the richest of all the tribe, the fiery Prometheus. There were several blanks in the rows it is true (nurserymen rather like to see them), for a great man had drawn on the stock to no small extent—Mr. Cecil Rhodes—and took the shrubs off by hundreds; but there were plenty left to make the Forest glorious. And then there were the masses of Mollis Azaleas, notably the standards—dense bouquets of beauty. Mr. A. B. made a dart for one of them, to read its name on a ticket; it was simply "sold." Another and another, with the same "name." At last he remarked, in a sort of disappointed way, "They are not all sold; are they, Mr. Paul?" "Oh, no; not all." "Then I want some, and please do not forget." It was rather firmly spoken, and Mr. Paul will, perhaps, "not forget."

Mr. Paul is becoming more and more interested in his new race of early hardy Rhododendrons. Some years ago he applied pollen of some of the rough recurving-leaved catawbiense varieties to flowers of the long flat glossy leaved Chinese Rhododendron Fortunei. He has numbers of resulting varieties flowering in various colours, and the effect of the crossing is unmistakeable. The "Catawbs" have given colour and boldness of truss, Fortunei large open flowers, like Azaleas, with long peduncles, and hence open trusses, the foliage varying, but mostly smooth. These seedlings are quite distinct in character, thoroughly hardy, and as a rule flowers decidedly in advance of the bulk of Rhododendrons in cultivation. A few have been named, and found favour, notably the Duke and Duchess of York. It is slow work raising and growing, flowering and selecting Rhododendrons and hardy Azaleas, and then there may be a hundred times more blanks than prizes; but Mr. Paul hopes he has fallen in for a few of the latter, though he seems to think more of lengthening the Rhododendron season by gaining a week or two at the beginning of it than anything else.

The soil of this forest nursery seems largely composed of Bagshot sand and gravel, darkened by humus, the result of the decay of vegetation through the centuries, though it may also

contain a trace of clay. It has only been brought into its present condition by much labour; but there is the reward not in Azaleas and Rhododendrons only, but in a grand plantation of Araucarias, and truly magnificent specimen Hollies, kept moveable; and, besides, Tea Roses grow with a freedom rarely seen, and must take up with "wigs" of roots from such a medium. Hybrid Perpetuals do not answer, but that is of small consequence, as there is not room enough for them if they would, and they are happy enough at Cheshunt, some five or six miles away. We must be "away," too, as we have lingered more than the intended quarter of an hour, and Mr. Paul now takes us to the "Drosera field," in which numbers of the little Venus' Fly-traps stud the swampy ground. We had not time to hunt for the Lycopods, and instead of dropping Mr. Paul at his cottage he had to endure a four or five miles drive along the London and Cambridge Road, right through the Forest to Epping, and stay there for a little while at a famous old-time hostelry.

As previously from the high ground we had looked down over far spreading Herts, now on the return journey we took the other side in which Essex was brought for a time within the line of vision; but we were soon among the trees again, passing through rustic rural Theydon. On one side the trees had been thinned for a distance, the appearance being somewhat park-like, the other side wild. While a little change may be desirable here and there, and fine trees opened out, it is easy to do too much thinning in a real "forest" like this, where, generally speaking, "nature unadorned" presents the greatest charm. No doubt Mr. McKenzie, the superintendent (whom we did not see) is aware of this, and considering his training under his father, the late respected Major, the forest should be safe in his keeping. Artists burst out in complaints from time to time, as is their wont, and they may perhaps do a little good. We saw nothing to complain about in an enjoyable drive through or past some 6000 acres—mountains and valleys of trees—Beeches, Birches, and Oaks, dappled in various tints of green. It was pitiable, however, to see the larvæ of the winter moth devouring the Oaks, though the observant "A. B." remarked, they let the Turkey kind alone—a hint for future planting.

We left Mr. Paul (to whom we were so greatly indebted) near his cottage, and on reaching Babylon again agreed that we had experienced a day of delight, and that we should not fail to keep the next appointment, if it fell on a rainy morning. "Come, haven't you done?" whispers someone, looking over a shoulder; "I am sure you ought to apologise." "I would if it wasn't holiday time, when they will excuse the Forest ozone," replied—THE SCRIBE.

SUMMER BEDDING.

(Concluded from page 477.)

No portion of the garden is more beautiful and interesting in the summer than the water garden. If you have the smallest stream of water running through any part of the garden it may be turned into a very beautiful and interesting feature, by making a number of small ponds or beds of water, to be planted with aquatics, and amongst and round about these pools may be made beds of Cannas, Castor Oil plants, Lilies, Hydrangea paniculata, Fuchsias, Eucalyptus globulus, and Japanese Iris (Iris Kämpferi). The ponds must be made of various depths to suit the different water plants, and should be in the full sun, and sheltered from rough winds as much as possible. The sides and bottoms of these ponds must be watertight by puddling with clay or cement, afterwards making a good mud bottom. The warmer the water can be kept during the summer the better the plants will thrive, therefore if your supply stream is a fast-running one have just enough water entering the ponds to keep them overflowing. The remainder of the water not required may be turned another way, and hardier moisture-loving plants grown by the side of it, such as Spiræas palmata, palmata alba, palmata elegans, Aruncus, astilboides, and japonica compacta; common yellow Iris, Iris Kämpferi in great variety, variegated Rushes, Bamboos, Lythrums, Lobelia syphilitica, hardy Carex, Bullrushes, Water Flags, Gunneras manicata and scabra, very noble plants with immense leaves, and not forgetting the Marsh Marigolds, Caltha palustris, palustris pleno and alba; Primulas japonica and rosea, Limnathes Douglasi, Saxifraga peltata, a beautiful flower, also Saxifraga Fortunei; Cypripedium spectabile, Sarracenia purpurea and Parnassia, while on the banks may be grown patches of Lilium lancifolium rubrum, roseum, album and Krætzerei, Montbretia crocosmæiflora and Pottsi, groups of Cannas, patches of Cowslips and Primroses, Narcissus, Fritillarias, Chionodoxas, Trilliums, Snowdrops, and Crocuses. The artificial ponds should not be made to look too formal, and if the sides are cemented let the green grass come over to meet the water, so that the cement may be kept out of sight.

In the first pond, with about 2 feet of water and 6 or 8 inches of mud, plant Nymphaeas gigantea (white), carolina (clear rosy pink); Nuphar

lutea (common yellow Water Lily), Nuphar advena (yellow American Lily); Nymphaea alba (common white Water Lily), Hottonia palustris (Water Violet), Aponogeton distachyon (Water Hawthorn), Stratiotes aloides, a plant like a Pandanus, with white flowers. In the next pond, with 1½ foot of water and 6 or 8 inches mud, which depth I find suits most of the Water Lilies best, plant in the centre Nymphaea Marliacea chrometella (cream coloured, a most perfect and beautiful flower, which will bloom freely from June till October), on either side Nymphaea Laydekeri rosea, a bright carmine rose coloured flower; and Nymphaea Marliacea carnea, a grand bloom of beautiful flesh colour. These should all be quite 4 feet apart. Now you have a good centre, and round about these plant the following sorts, 4 feet apart:—Nymphaea odorata sulphurea (a sulphur yellow, with large blooms and marbled leaves), Nymphaea odorata rosea (very fine rose colour), Nymphaea Marliacea albida (a grand white), Nymphaea odorata Exquisite (rather dark rose colour, but not quite such a strong grower as many), Nymphaea flava (bright yellow), Nymphaea Laydekeri liliacea (a new colour amongst hardy Water Lilies; this I think will prove a grand thing, but it is too new to say much about at present), Nymphaea candida (white), Nymphaea rubra (rather darker than carnea, in other respects very similar), Nymphaea alba plenissima (a perfectly double white). These will produce a fine display of flowers that will be greatly admired by all who see them in bloom. I know no flowers which look so beautiful on a hot summer's day.

In pond No. 3, with water 1 foot deep and 6 inches of mud, a great variety of plants can be grown, and most of these will stand above the water, both foliage and flowers. These look best in groups, kept to their sorts. In the centre place a group of Arums, Richardia æthiopica, with Pontederia cordata (blue spikes of flowers), planted about 4 feet from the Richardias on the one side, and Butomus umbellatus, the pink flowering Rush, on the other. The two remaining sides can be furnished with Sagittaria montevidensis, which has long spikes of white flowers with dark chocolate centre. This is a fine plant, but it should be protected in the winter. The remaining part of the pond can be filled with groups of Sagittarias japonica, single white flower; japonica pleno, a splendid pure white double variety; gracilis, a very pretty, graceful variety, white single flowers; and variabilis, white flowers, with darker centre, and closer set up the stems than the other varieties; Peltandra virginica, a small Arum-like plant; Arontium aquaticum (golden club-like flower), and Alisma plantago, panicles of small white flowers. These should be all planted with a good space of water between each group, and in that space small floating plants may be utilised, such as Nymphaeas pygmaea, pygmaea helvola, and Nuphar Kalmianum, sagittæfolium. The water in the fourth pond should be 6 to 9 inches deep, with mud and plenty of gravel stones at the bottom. All the following plants will do well here: Menyanthes trifoliata (a feathery pale pink flower), Calla palustris (white), Limnobaris Humboldtiana (a very beautiful pale yellow), Alisma natans (white), Villarsia nymphaeoides (yellow), Villarsia ovata (panicles of yellow flowers), and Utricularia vulgaris (small yellow spikes). All the plants I have mentioned for the various ponds might be grown in one, if sufficiently large, and the water at various depths, from 2 feet to 6 inches. Close to the edges, touching the water, may be planted Cardamine pratensis, both single and double; Calthas of sorts, Saxifragas Fortunei and peltata; Sarracenia purpurea, Cypripedium spectabile, small herbaceous Spireas, and Parnassias.

I find the best way of treating the choicer sorts of water plants is to place them in Orchid pans, in well decayed loam, and covered with half an inch of coarse silver sand, then sink the whole into the mud. The sand keeps the soil from floating out of the pot when sinking it, and afterwards, the plant will soon root through the holes and over the top of the pot and take care of itself. The commoner sorts may simply be pegged down to the bottom with strong, long, wire pegs, or sunk by means of fastening a piece of lead to the roots. Some of these Nymphaeas make very long, strong, and large leaves, and if not carefully looked after will soon spoil the weaker growers, so the old leaves and those in the way should be kept pulled off from time to time. Near to these beds of water plants a good group of mixed Cannas, with a few herbaceous Phlox of different colours dotted amongst them looks well, and large Fuchsias, with Erythrina crista galli and Swainsonia alba, are also effective.

A pretty feature near the ponds in our garden is a large irregular mound, with a common Thorn in the centre, and a few flowering shrubs, planted a distance apart, on the top. Round the outer edge of these shrubs are planted Hydrangea paniculata, and amongst these shrubs in the summer are dotted in Cannas of various sorts and clumps of herbaceous Phlox. In the sloping bank tubs of Lilies have been let in here and there, and all round irregular stones are fixed, the spaces between being filled up with all sorts of small-growing plants. In August and September it looks charming, and is always much admired; perhaps more so because it is something out of the usual way of bedding. —(Read by Mr. W. TOWNSEND at a meeting of the Reading Gardeners' Association.)

POISONOUS BUTTERCUPS.—The Lancaster coroner recently held an inquiry into what he described as one of the most extraordinary poisoning cases that had come under his notice. A boy, aged four, named William Foxcroft, ate some Buttercups—one of the commonest flowers gathered by children—and died in a few hours from irritant poisoning. It was stated that Buttercups belong to an extremely poisonous class of plants. A verdict of "Accidental poisoning" was returned.

INSECT INVASION.

So the lightning performer with the pen (see footnote to his article, p. 479) is not a gardener. I rather thought as much. I am referring, of course, to our well-lettered friend, "Y. B. A. Z." I am really not concerned about the arrangement of the familiar symbols first from end to end and *vice versa* of the alphabet (nearly), and next absolutely. I have sometimes wondered what they meant, but never whose they were. The only meaning that I could attach to them was that their genial owner was a Young Bachelor of some Association of Zoologists. If that should be so, I quite agree with the septuagenarian young bachelor that there is "some charm about a *nom de plume*," and I would not have this one of more than thirty years wear and tear changed for the best insect antidote in the world. It is, apart from its familiarity, altogether too picturesque.

I have, in a curious and unexpected way, made a discovery in which I am sure our friend will be interested. He will see a case of history repeating itself, and, at the same time, admit that he incited curiosity as was recorded, as near as I can calculate, thirty-two years, four months, and ten days ago. Now Mr. "Y. B. A. Z.," I can almost fancy hearing you ask yourself, What's coming next?

Do you remember inviting a gentleman who had been adversely criticising Malay fowls to come and see yours and be confounded? then do you remember when he arrived that you would not let him see them till after lunch? and next, do you recollect raising the cover at table and revealing a roasted Malay, which the critic was obliged to confess was "most excellent?" Yes, all this will come back to you as a pleasant episode, when, in a very old-fashioned way for a young man, you had the critic "on toast."

Again, do you not remember the way in which your "cognomen" incited interest then, not to say vain imaginings; how the critic was asked whether the four letters stood for a lady, and, if so, whether she was married or single, short or tall, dark or fair; but he thought prior to his visit they belonged to a gentleman—an Oriental?

Possibly you may remember his reasoning it out in this way—"I looked at the letters, looked again, and then broke out triumphantly: I have it; he is a Persian gentleman; remove the periods between the letters and have but one capital, and the Oriental name comes out clearly enough in this way Ybaz." He imagined you as a merchant from Shiraz or the Vale of Cashmere, expected to see you in Persian costume, and to hear you quote the poems of Hafiz. But when he met Ybaz he grasped the hand of a thorough Englishman, and you were friends at once; then he says, "Ybaz exclaimed, 'There is the bond,' pointing to our Journal."

This is very pleasant. The Journal has made many friends between its readers, and than this, I think, evidence has not been wanting throughout its career that nothing could be more gratifying to its editors.

No, I am not the critic in disguise, and not the first to be interested in the "alphabeticals;" and you, Mr. "Y. B. A. Z.," ought to be glad to incite the imaginations of your readers as a relief from the dull prose and grind of toil which tends not to gladden the heart.

But how do I know the details of the meeting and the Malays, of the Ybaz and the critic, and all the rest of the doings of that day in the West which you are now in fancy living over again and enjoying? Are they not written on page 98, vol. viii. of the *Journal of Horticulture*, the weekly issue of January 31st, 1865? No, I did not hunt the narrative out because I did not know it was in less than a week ago. Entering a library I took the volume to look for something (that was not in), and the first casual opening was at the very page on which the narrative of "Wiltshire Rector" appears—a curious "find," under the circumstances. It was, and is, much more interesting to me than insects, and I am asked (on page 479) to say but very little about them.

I should be surprised if I ever suggested that "fumigation cures red spider." Vines and Peach trees have just been closely scanned, but not a solitary mite can be found, I think, by anyone. This was not always so. The eggs were destroyed in the winter, as they easily can be by a method that has over and over again appeared in the Journal; then with thoroughly healthy growth in root, branch, and leaf, a genial atmosphere and pure water syringings, of Peaches regularly, Vines very occasionally, both are as they are, absolutely clean, as I shall be very pleased to show the old journalist when his "time and temper" permit. As in the case of "spider," there can be no aphides without eggs, nor eggs without insects, and these can easily be kept out of houses by half strength fumigations that would be necessary to kill a good crop of the pests. It would no doubt be the same with vapourisation—always before an insect is seen—at fortnightly or three-weekly intervals in spring and early summer, according to the weather, much less frequently as the season advances. Then, if no mistakes are made in watering, ventilation, and general management, plants may be, and are, kept absolutely clean. It is a case of no eggs no insects, or no insects no eggs, whichever way you like to put it. Of course, not half nor perhaps a tenth part of aphides come direct from eggs, but these are the original source of supply.

A point too often overlooked needs to be strongly enforced. Many persons, and not amateurs only, invite insects by errors in watering, heating, ventilation, and general routine under which the health of plants is so impaired that their enemies seem to find them by a sort of instinct, or in other words they choose the points of least resistance. Of this there can be no doubt whatsoever.

There is neither novelty nor difficulty in keeping insects out of fruit and plant houses, when the best cultural skill is displayed, and means

are afforded for accomplishing the object. I have lately been through two very large gardening establishments in which the work is of the best, and not an insect of any kind was seen on plants, Vines, or trees in the scores of houses in which they are grown, and I could go into a dozen gardens and find the same gratifying immunity. The most successful cultivators do not kill insects; they prevent them. It is pleasurable to hear that "Y. B. A. Z." is practising successfully on the same lines, and I hope he will remain in his situation for yet many years to come.—W.

ROSE SHOW FIXTURES FOR 1897.

- June 15th (Tuesday).—Ryde.
 „ 16th (Wednesday).—York.†
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 23rd (Wednesday).—Richmond, Surrey.
 „ 24th (Thursday).—Colchester.
 „ 25th (Friday).—Maidstone.
 „ 26th (Saturday).—Windsor and Dorking.
 „ 29th (Tuesday).—Canterbury, Hereford, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon, Ealing, Farnham, and Reading.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 6th (Tuesday).—Diss.
 „ 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
 „ 8th (Thursday).—Bath, Bedford, Farningham, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.

 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.
 „ 28th (Wednesday).—Chester.*
 „ 31st (Saturday).—Liverpool.*

* Shows lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

THE WALTHAM CROSS ROSES.

MESSRS. WM. PAUL & SON invite inspection of their great show of Roses, which will commence flowering in the middle of June, and which promise to be in fullest bloom about the middle of July, followed up by a succession of flowers to the middle of October.

COMMENTS AND IMPRESSIONS.—MANURES.

(Continued from page 479.)

THE first season after planting the young Roses in the three beds made good growth, but the vigour was more marked in the guano bed than the others, the stable manure coming next, and the bonemeal third; but some differences were observable; for instance, *La France* and *John Hopper* in the guano bed were much in advance of the same varieties in the stable manure, while the growth of all the varieties was very uniform where bonemeal was used. A few flowers were obtained, but nearly all these were from beds 1 and 3, the guano having apparently had too stimulating effect, for only the two varieties above named flowered, and they had imperfect blooms. In several cases it was fancied that the effects of the bonemeal were shown in more substantial flowers, but the results were not sufficiently clear to enable an exact judgment to be formed.

In the autumn the plants were all cut-in rather hard, and the applications were repeated in the same quantities and at corresponding dates. The results in the following season were much more apparent than before, both in growth and flowers. As regards the former the greatest vigour was shown by all six varieties in the guano plot, those in the stable manure plot were next, and the plants in the bonemeal bed were the least vigorous, but they were strong enough, and again were more uniform than the others. The order was reversed in the floriferousness of the plants from the respective beds, for those in No. 3 plot (bonemeal) produced quite 10 per cent. more flowers than either of the others; the blooms were larger and of more substance, and the colours purer. *La France* showed the greatest difference in these respects, and *Niphotos* the least.

There was enough in these observations to justify further research, and I had determined to try the effects of both nitrogen and phosphoric acid in a simpler form, when a friend called my attention to the fact that I was partly repeating experiments previously undertaken by the

veteran rosarian, Mr. William Paul. Though possessing a tolerable library of Rose literature, I unfortunately had not a copy of the "Rose Garden;" but I subsequently found that Mr. Paul's experiments had taken this form. Six beds of Tea-scented Roses received dressings respectively of bone dust, burnt earth, nitrate of soda, guano, pigeon dung, and thoroughly decomposed stable manure. To give Mr. W. Paul's own words, "The guano produced the earliest effects, causing a vigorous growth, which continued till late in the season; the foliage was large and of the darkest green, but the flowers on the bed were not abundant. The shoots did not ripen well, and were consequently much injured by frost during the succeeding winter. The bed manured with burnt earth next forced itself into notice; the plants kept up a steadier rate of growth, producing an abundance of clean well-formed blossoms, the wood ripened well, and sustained little or no injury from frost. The results attendant on the use of the other manures were not remarkable; they had acted as gentle stimulants, the nitrate of soda and bones least visibly so, although they were applied in the quantities usually recommended by vendors." It is rather unfortunate that the exact quantities used are not given, nor are the dates of application. Perhaps Mr. Paul could say what they really were, and also whether these very interesting experiments were continued in subsequent years.

Circumstances compelled me to relinquish my experiments after a third season's trial, but in that year superphosphate of lime was substituted for the bonemeal and sulphate of ammonia for the guano, both being given in the same quantities as the manures whose places they supplied. Perhaps it would have been more satisfactory if fresh beds had been planted for these experiments, but as that was not convenient we had to be content with what could be learned from those already planted. The growth followed practically the same order as before, but the flowers from plants in No. 3 bed (superphosphate), both in numbers and substance, were much superior to the others. Since then similar experiments have been tried at times, but not in quite such a systematic way as I should wish. The general results have, however, convinced me that a small quantity of stable manure on the heaviest soils, with superphosphate and a little burnt refuse or potash, gives far better returns, well-developed growth, and substantial blooms than an excessive use of stable or farmyard manure, either in the soil or as a top-dressing for assisting the plants in the spring. Still I should like to see what others have to say on this matter.

The keen north-easterly winds have increased the mischief wrought by recent frosts amongst our Roses, and we are rather dismayed by the appearance of the foliage, while we are waging war with numerous leaf enemies. But every rosarian must be of a hopeful nature if he desires success, and so we are looking forward to the later realisation that June or July should bring.—A MIDLAND ROSARIAN.

NEW ROSES.

DURING a recent visit to Waltham Cross, which is known as a great centre of English Rose cultivation, I had the pleasure of seeing that uniquely coloured Tea Rose *Empress Alexandra of Russia*, which I think is likely to make a good impression when it is introduced by its raiser into the wider regions of general cultivation. It is in all respects a worthy successor of *Medea*, one of the finest of existing yellow Tea Roses, not inferior in any respect, save that of climbing capability, to the *Maréchal Niel*, which it (*Medea*) equals in size and form, and transcends in perpetuity.

His latest Tea Rose, which Mr. Paul told me was associated with the name of the *Empress* by her own permission, has been described by the Waltham rosarian as a "rich lake-red shaded with orange and fiery crimson," but indeed its brilliant colour is arduous to depict. The plant is manifestly of upright habit and vigorous character, two important characteristics. It has deservedly received an award of merit from the Royal Horticultural Society. Waltham Standard and Queen Mab are also very beautiful, the former being a Hybrid Perpetual of brilliant carmine hue, somewhat resembling *A. K. Williams*, of even stronger growth and finer foliage than that far-famed Rose; while the latter is a China variety of bright apricot colour slightly suffused with orange, producing larger flowers than any other Rose of its own special class with which I am acquainted. Admirable as it is at Waltham Cross under glass, it is even finer and deeper in colour when grown in the open air. Mr. Paul's *Enchantress* I have already spoken of in previous contributions.

These, with *Lawrence Allen* (Cooling & Sons, Bath, 1896), *Muriel Grahame*, *Helen Keller*, *Marjorie* and *Mrs. W. J. Grant*, are probably the finest of recent British introductions, for several of which we are indebted to the great Newtownards rosarians.—DAVID R. WILLIAMSON.

INFLUENCE OF ETHER ON PLANTS.—It is reported in the daily press that the United States Consul at Copenhagen, has made a report to the department of state giving a description of an interesting discovery in the physiology of plants made by *Johannsen* of the agricultural high school of Copenhagen. The discovery is that plants are susceptible to the influence of ether or chloroform, but in their case the effect is to awaken them instead of putting them to sleep, as would be the result with human beings. Also the plants are made to grow with great rapidity in or out of season, a fact of importance to gardeners and florists, providing the statement is correct.

BAPTISIA EXALTATA.

SUCH is the name of the plant of which "Devonian" sends us a specimen for identification. It is a North American plant, whence it was introduced to this country in 1812, but it is now seldom seen in gardens. Occasionally in old borders of herbaceous plants specimens are seen of this and other Baptistias, though in good soil and with ordinary attention they are much more effective than many occupants of our gardens. Clumps, with stems 3 or 4 feet high, and bearing large racemes of bright blue flowers (fig. 98) produce a fine display, and are very useful as a background to dwarfier plants.

FLOWERS IN THE HOUSE.

TWO great principles underlie the arrangement of flowers in vases or glasses, just as they do the arrangement of plants for effect. We sometimes see what are described as light, graceful, and elegant arrangements of flowers, which instead are a conglomerated mixture of flowers, Ferns, and graceful sprays of foliage. The filling of flower glasses for room decoration, if considered as a work of art, should be done according to the rules of art and beauty; and as the virtue of art consists in producing the greatest effect with the least amount of work, the simpler our floral arrangements are the more pleasing and interesting they will be.

Cut flowers, like plants, should be classified as either characterised by beauty of form or beauty of colour. Those possessing the former should be arranged so as to show individual beauty, not crowded or massed. If any greenery is used it should be of the lightest description, and not in over-abundance. Flowers only distinguished for purity, delicacy, or brilliancy of colours must be massed, and are better without greenery. If any foliage is used it should not in any case tower above the flowers, as by so doing it detracts from their distinguishing qualities.

It is imperative that only one kind of flower be used in the same glass or vase, and in some instances only one colour. Avoid the mixing of different tints or hues of one colour. If contrasts in the same vase are desirable they are almost better to be carried out by the addition of coloured foliage, as Allamandas, with sprays of Cissus discolor. Bougainvillea glabra, with sprigs of Copper Beech or Prunus Pissardi, red Cactus Dahlias and sprays of Acer Negundo variegata. The rich crimson Cactus Dahlia Juarezi, and the silvery foliage of either Centaurea candidissima or Cineraria maritima, Mignonette, and purple Sweet Peas.

The selection of receptacles suitable in shape and form is one of the great points in the proper arranging of flowers, the flowers possessing beauty of form, characterised by dignity, grace, slenderness, and chasteness of outline or substance. In this category may be included almost all bulbous and rhizomatous-rooted plants, and we observe that Nature places them on erect stems, advancing well above the leaves. The receptacles for them should be in proportion to the size of flower or length of stem, whether of glass, enamelled earthenware, or porcelain, the neck being narrow, cylindrical, or bottle-shaped. The trumpet glasses, so often used, are altogether unsuitable, and with heavy flowers are liable to be upset. All Orchids are to be included in the preceding category, besides Pancratiums, Eucharis, Lilliums, Amaryllis, Irises, Freesias, Gladioli, and Clivias.

Almost all herbaceous flowers should be cut with a full length of stem, and be massed in tall earthenware vases, removing all leaves from the stem that will be in the water. Pæonies, Phloxes, Pentstemons, Sunflowers, annual and perennial Delphiniums, are included in the above. Annuals may be massed in trumpet glasses—blue Cornflowers, Corn Marigolds, Shirley Poppies, Clarkias, Sweet Sultan, and Godetias. Sweet Peas are best massed in bowls, with streamers if put on pedestals, and they are very pretty so placed near fireplaces or couches.

Roses, Carnations, double Zonal Pelargoniums, Scabious, and German Asters are very effective massed in separate colours in bowls, low earthenware pots, or two-handled cups. Violets are nice in tumblers. Flat dishes may be arranged with Stephanotis, without foliage, like a dish of wax. The same with single flowers of red and white Lapagerias; also in this way Dipladenias, Ixoras, Rhododendron Princess Royal, Gardenias, Jasmine, Azalea indica, Allamandas, Rondeletia, Cactus Dahlias, with foliage as before mentioned, Plumbago capensis, and Ivy-leaved Pelargoniums Madame Crousse (pink) and Souvenir de Chas. Turner (rose) are telling when arranged in glass sugar basins.

Vases standing high on cabinets, mantelpieces, or pianos should have flowers of a naturally drooping character, as Bougainvillea, Clerodendron Balfouri, Habrothamnus, Deutzia gracilis, Clematis, Begonia insignis or fuchsoides. Flowers with hardwooded stems ought to have a strip of bark peeled off the stem, so as to enable them to suck up the water, which must be kept perfectly fresh by frequent changing. It will be seen that by the above remarks that it is intended that flowers should be arranged according to the true length of their flower stem, and glasses or vases should be proportioned accordingly.—F. STREET.

ELLAM'S DWARF EARLY CABBAGE. — This variety was sent out by Messrs. Veitch about twenty years ago, and is still one of the best early Cabbages grown. From a quarter containing 3000 plants not one has bolted. They are all heart, of exquisite flavour, and as they are grown only 15 inches apart, a few acres of them at this season would be valuable.—GEO. SUMMERS, Sandbeck Park.

SCHOOL GARDENS.

"HERGA'S" note on this subject, at page 435, induces me to say a few words in the same direction. He is, however, wrong in assuming that district councils (rural) have power to provide allotments for the working class. Urban district councils have, but in the rural districts that power is in the hands of the Parish Councils. They have, however, no power to provide ground for school gardens. That can be done in the case of elementary schools only, through the managers, or in the case of County Council groups through the County Councils, or their technical education departments.

It is hardly satisfactory to learn from the Education Department report of the year ending August 31st of last year that only forty-two schools throughout England and Wales took "cottage gardening" as a special subject, and of these only twenty-seven earned a grant, the

FIG. 98.—BAPTISIA EXALTATA.

inference being that the subject was either poorly taught or taught without the aid of school gardens. The total number of boys attending were 475, and of this number 165 earned the lower or 2s. grant only, having attended only twenty hours during the year, whilst 310 obtained the 4s. grant, having attended forty hours. It must not be overlooked, however, that the subject of "cottage gardening" was introduced into the Education Code in 1895 only; hence last year's results were those of the first year's experiment.

Whether "cottage gardening" as a special subject, taught with the aid of school gardens, either under or by a capable school teacher or by some local gardener, will be more widely taken up in the rural districts depends no doubt upon the action of school managers. But in their anxiety to make money through grants there is too much reason to fear that other subjects less practical and useful may be preferred to "cottage gardening"—especially that in this case both ground and tools have to be provided. It sounds strange to hear that even for such important educational purposes it is often difficult to obtain even some 10 or 12 rods of ground in the rural districts, but that such is the case is likely to seriously affect the wide spreading of practising school gardens. Whilst Parish Councils can obtain as best they can allotments for adults, as I have said, they have no power to obtain them for children, but if

any acknowledged allotment holder, after getting possession, chose to allow a portion or all of his plot to be so applied I believe that may be so.

Turning to the work done in the direction of supplying school gardens by County Councils, I believe that Surrey stands foremost. For several years it has promoted the formation of what are called "school," but are really boys' "continuation gardens." Formerly lads either of or away from school were esteemed eligible to have gardens, but since cottage gardening has been made an elementary school subject, boys attending school cannot be holders of continuation garden plots under the C.C. Technical Education Committee. That has led to two or three transferences, but still very few. In the great majority now lads are taught in the gardens who have not only left school, but are of the age of fourteen and upwards. Whilst in Surrey there were last year twenty-six groups of County Council gardens, and a total of 357 boys working them, there were of Education Department groups only three. Three other groups are being added this year. However, the numbers are, compared with those controlled by the County Council, enormously disproportioned. The County Council gives a minimum grant to each garden of 2s. 6d., and a further merit grant of 1s. 6d. or 2s. 6d., as the case may be. Their inspection, which is of the most careful description, is conducted by an able gardening expert, who does know what gardening is, whereas departmental inspectors, as a rule, are of gardening absolutely ignorant.

A notable case occurred in one village in the county of the difficulty of securing even a few rods of ground. A very earnest schoolmaster and an equally enthusiastic gardener were most anxious to establish continuation gardens. They worked hard in securing suitable land, and had the sanction of the Technical Education Committee for their arrangements, but yet, and in spite of the strong desire locally manifested, that the gardens should be provided, yet in the end no ground could be secured, although so trifling a portion was required. Clearly in such matters as this it is evident very drastic powers to secure land for educational purposes should be placed in the hands of local authorities, and failing them, then be vested in the County Council.—A. D.

HARBORNE HALL.

AMONGST the more noteworthy suburban residences situated around Birmingham is that belonging to Walter Chamberlain, Esq. The estate was purchased about sixteen years ago, and has since undergone extensive improvements, and now forms one of the most desirable of domains. The mansion and pleasure grounds occupy a commanding position on the highest portion of the estate, with a full view of the celebrated Clent and Lickey Hills, the broad expanse of intervening valley, and are fully exposed to the south and west winds.

In extending the area of the pleasure grounds a considerable acreage of the estate adjoining the old portion was laid under contribution, and designed mainly by Mr. Chamberlain himself. In the carrying out of this he found an able coadjutor in his present intelligent head gardener, Mr. C. R. Bick, who has the general superintendence of the estate. In altering both the old and new portions, it was determined, partly by way of experiment, to introduce a considerable number of the choicer species of Conifers, planted in masses on the more exposed sites, with the hope of their future establishment, but the acclimatising ordeal eventually proved too drastic for several of the tenderer species. In the general embellishment of the grounds a fine assortment of trees and shrubs was introduced—notably large masses of the choicer Rhododendrons, which at the time of the writer's visit a few days since had begun to effectively unfold their gorgeous inflorescence.

In the re-designing and formation of the grounds and spacious lawn contiguous to the house, the introduction of the usual formal parterre for bedding-out plants was ignored, the object being to preserve as much as possible a lawn-like aspect in the foreground as well as further on down the slope, extending towards the extreme boundary of the grounds. Ample provision, however, was afforded in other positions for the display of herbaceous and annual flowers, for which there is a great demand in the cut state for room decoration. Roses are largely grown in the compact roserie, enclosed by a formal Yew hedge ranging about 5 feet in height, and affording an excellent shelter from the east winds. *Appropos* of the demand for cut flowers, it may here be remarked that the whole of the glass structures are solely devoted to plants for conservatory and room decoration, including the supply of cut flowers. The cultivation of forced fruits is entirely discountenanced, Mrs. Chamberlain's requirements and love of flowers necessitating the utilisation of every foot of glass at command.

The construction of a pool in which various exotic fowls find a home entailed a vast amount of labour and expense, the upper portion of it having been furnished with a rockery by Messrs. Pulham & Son with happy effect. A large assortment of shrubs, Ferns, and waterside plants is there, the whole being established in happy combination amongst the rockery and on the deep steep banks around, whilst a considerable proportion of the pool is canopied over and around by a large group of tall old Elms and other kinds of trees, under which the grass is allowed to grow in semi-wild state, chiefly for the sake of the carpeting of Bluebells and other wild flowers therein. Altogether the *tout ensemble* has proved a gratifying success. Another good example of the formation of an ornamental pond is to be seen within a short distance of the mansion, and considerably differing in character from the foregoing. It also entailed a heavy expense and difficulty in its

formation, lying, as it does, over a substratum of gravel—consequently, had to be efficiently puddled with clay to the depth of 12 inches, and close up to the turf edging of the sloping lawn. In its centre is an islet completely possessed by a mass of *Polygonum cuspidatum* in conjunction with masses of *Typhas angustifolia*, *latifolia*, and *minima* springing up around from the water; whilst other parts of the pond are furnished with a variety of aquatics such as *Nymphæas*, *Aponogeton distachyon*, the pretty Bog-bean (*Menyanthes trifoliata*), *Sagittaria sagittifolia*, *Caltha palustris* (the Marsh Marigold), *Villarsia nymphaeoides*, which, pretty though it be, is apt to make itself too predominant—consequently necessitates frequent checkings. The margin of the pond is richly embellished with waterside plants. The most noticeable are *Cyperus longus*, *Sparganium racemosum*, *Carex pseudo-cyperus*, *Acorus calamus*, *Pontederia cordata*, *Butomus umbellatus*, *Epilobium angustifolium*, *Carex riparia albo-marginata*, *Orchis maculata* and *mascula*, *Petasites vulgaris*, *Gunnera scabra*, *Rheum officinale*, *Spiræa aruncus*, *S. filipendula flore-pleno*, *S. palmatum* and *S. astilboides*; *Eulalia zebrina* in a highly flourishing condition; *Funkias variegata* and *F. ovata* very striking. A large mass of *Arundinaria Metake* growing to a height of from 8 to 10 feet is extremely effective, and evidently enjoys growing in close proximity to the water.

Ferns are represented by such as the Lady Fern (*Athyrium filix-fœmina*), and the Royal Fern. Flourishing also are several plants of *Iris Kämpferi*, and, with very pleasing effect, small plants of *Primula rosea*, whilst an additional charm is lent by the verdure-clothed masses of tufa, more or less in irregular form, projecting into the water, in which gold-coloured carp, disport themselves—good evidence of its purity.

These imperfect notes of this interesting domain would be incomplete without reference to a very fine plant of the charming blue-flowered *Ceanothus Veitchianus* growing against Mr. Bick's house. This plant was in a mass of inflorescence at the period of our visit, and bearing strong evidence of claim to a more extended recognition of its merits and culture elsewhere than has yet been accorded to it, whilst its hardiness admits of no doubt.—G.

MANCHESTER WHITSUN SHOW.

WHEN we came to take our eye over the gorgeous display of Orchids brought together under the roof of the grand exhibition house at the Botanical Gardens, Manchester, we can only express ourselves in the one word, "wonderful!" or agree with Mr. Burberry when he remarked that it was the finest show of Orchids he had ever seen brought together. Mr. T. Statter (Chairman), and Mr. Thompson, Stone, whose love for them is so great, sincerely hoped that the public would appreciate such a treat.

Coming to the exhibits, the glory of the Orchids almost dwarfed everything else. How beautifully one end of the exhibition house was made perfect by the foreground of Orchids, backed up by the grand stove and greenhouse plants from Cypher of Cheltenham. So, too, was the left hand bank by the veteran, Mr. Stevens of Stone. Looking into the annexe what beauty presented itself. The gold medal Cannas from Paul & Son, all so brilliant; the mass of colour made by the hardy cut flowers from Barr & Sons, and Dicksons, Limited, Chester; the soft shades of colour in the Worcester Clematis; the noted Forest Hill Begonias and Caladiums, to the left of which were Cutbush's fine pot Carnations, and to the right the charming miniature rockwork, filled with the most interesting and rare alpine plants from Backhouse of York. A gold medal was bestowed also for this firm's group of Orchids and miscellaneous plants—an interesting show; whilst far beyond in the distance, planted out on mounds, were the notable Rhododendrons from Bagshot.

The highest award (the Society's large gold medal) was taken this year by Charlesworth & Co., Bradford, for a very beautiful collection of Orchids. A first-class certificate was awarded for one of the firm's introductions, staged by them for Mrs. Briggs Bury, Bank House, Accrington, and named *Lælio-Cattleya "Iolanthe"* with deep purple lip, from *Cattleya Mossiæ grandis* crossed with *Lælia purpurata*. Also lovely were *Lælio-Cattleya Lady Wigan*, from *Lælia purpurata* *Russelliana* crossed with *C. Mossiæ aurea*; *Cypripedium Laysenianum*, a cross between *bellatulum* and *barbatum* Crossi, which received an award of merit; *Lælia purpurata* *Backhousiana*, *Cypripedium Goweri* *magnifica* (grand form), *Cypripedium Morganæ*, and *Oncidium macranthum*.

Messrs. F. Sander & Co., St. Albans, secured a gold medal for a charming collection of Orchids and new and rare plants, splendidly staged. The gem of the show was undoubtedly the grand *Lælio-Cattleya* *Queen Empress*, from *Cattleya Mendeli Victoria* crossed with *Lælia purpurata* *Empress*. It is a veritable gem, with pure white sepals and petals, orange throat, and an intense crimson-purple lip. It was marked "sold." A F.C.C. was granted to *Sobralia Veitchi*, with rose sepals and petals, lip of deeper rose, and orange throat; also for *Davallia hirta*, a deep-coloured strong-growing species, likely to come to the fore. In all this firm secured six A.M. and a botanical certificate. Messrs. W. L. Lewis & Co. always count for something, and they were even better represented than on any previous occasion. They were worthily granted a F.C.C. for *Cattleya Hardyana* *Lewisi*, a flower with an immense coloured lip. The *Cattleya Mossiæ* were very fine throughout, and the other attractions were *Cypripedium Aylingi*, *Gertrude Hollington* and *Stonei*.

Mr. James Cypher, Cheltenham, secured A.M. for *Lælias purpurata* Meteor, Schofieldiana, and Duchess; also for *Cattleya Mossiæ striata* (very pretty). Mr. A. J. Keeling, a new comer from Bradford, made his *débüt* with a choice little collection, containing much variety.

Amongst amateur growers the chaste and beautiful *Cattleya Mossiæ* var. "M. Cahurza," was probably an attraction to all, as it richly deserved to be. In it, A. Warburton, Esq., Vine House, Haslingden, has a treasure. The form is perfect. It is most floriferous, having snow-white sepals and petals, with a lip partaking after the var. *Reineckiana*. It secured a F.C.C. Mr. Warburton had an award of merit granted for *Cattleya Mossiæ*, "Jubilee," having an exceptionally fine lip. D. B. Rappart, Esq., Liscard, as on the previous day at the Orchid Society, secured a F.C.C. for *Cattleya Mossiæ* in the way of C. *Reineckiana*, but very much finer, the Committee unanimously naming it *Catt. Mossiæ Rappartiana*, a chaste variety with white sepals and petals of rare substance and pale lip, dashed with bluish slate.

For the best miscellaneous collection of Orchids in bloom (amateurs) Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, arranged a charming display, the grand *Odontoglossum* for which Mr. Thompson is so noted being splendidly represented. E. Ashworth, Esq., came a prominent second, handsome *Lælias* and *Cattleyas* showing to great advantage. J. Richardson, Esq., Altrincham, was third. In the nurserymen's class Mr. James Cypher, Cheltenham, arranged his group with consummate taste, securing the first award. Most noticeable were *Lælia purpurata* in variety, fine *Odontoglossum crispum*, and the lovely *Thunia Marshalli superba*. Mr. Jno. Robson, Bowdon, had for second honours a choice display, comprising *Cattleyas* and *Dendrobiums* well grown and of much merit, also *Lælia tenebrosa*; but the whole group was much dwarfed by a too formal arrangement.

For the best collection of *Cattleyas* and *Lælias* in bloom Mr. Johnson, gardener to Thos. Statter, Esq., Stand Hall, Manchester, had a handsome stand relieved by Maidenhair Fern. *Lælia purpurata splendens*, *L. purpurata Statteriana* and *tenebrosa*, *Cattleyas Mossiæ Mendeli* and the beautiful C. *Mossiæ Reineckiana* were fine. Mr. James Cypher was a moderate second, *Cattleya Mossiæ* being good.

Mr. Cypher was the only exhibitor for ten stove and greenhouse plants, but as usual they bore the imprint of good and thorough culture. *Pimelea Hendersoni*, *Erica ventricosa magnifica*, *Spenceriana* and *depressa*, *Clerodendron Balfourianum*, *Aphelxis macrantha rosea*, *Hedera tulipifera*, and *Anthurium Scherzerianum* were shown. In the amateur classes Mr. Wilkes, gardener to Miss Lord, Ashton-on-Mersey, won with six stove and greenhouse plants, one foliage plant, one stove plant in bloom, with well-grown *Dendrobium densiflorum*, also for six fine-foliaged plants; but the collection was not up to the average for this season of the year.

There were three groups of plants arranged, Mr. Wilkes, with his usual good taste, winning with a light and elegant arrangement. Mrs. Blair was a good second. In the nurserymen's section Mr. A. J. A. Bruce, Chorlton-cum-Hardy, was adjudged the winner, the Bamboos giving great effect, otherwise the group was not up to former years. Messrs. R. P. Ker & Sons, Aigburth Nursery, were placed second.

Cinerarias were fairly well exhibited, Mr. Wilkes winning. *Calceolarias* and *Gloxinias* were moderate, E. Thwaites, Esq., and B. Woodrow, Esq., being the successful exhibitors. For a collection of twelve herbaceous and alpine plants J. Brown, Esq., Longfield, had a fair exhibit. The same exhibitor won with six pretty pot Roses, also for twelve pots of Pansies. A small but healthy collection of ten exotic Ferns secured the prize for Mrs. Blair. Messrs. W. & J. Birkenhead exhibited ten hardy Ferns fresh and in beautiful variety. *Coleus*, *Tuberous Begonias*, *Pelargoniums*, *Zonal* and *Show*, were really so moderate as to call for no comment, a fact to be much regretted.

Mr. Wilkes again showed much ability by his arrangement of a table of plants for effect. For not less than fifty Carnations in pots Messrs. W. Cutbush & Sons secured the gold medal. *Malmaisons* were numerous represented, some fine new ones bearing the names of Princess May, Prime Minister, Mrs. Everard Hambro, Reginald Godfrey, and Ness being much admired. Messrs. Jno. Laing & Sons secured the small gold medal for *Begonias*, F.C.C. being awarded to Hon. Cecil Rhodes, an intense double scarlet; Lady Pearson, a huge double salmon; and Admiral Rawson, a giant single orange scarlet. The same firm had a choice bank of *Caladiums*, so well known as to make comment superfluous. A gold medal also went to Messrs. Paul & Son, Old Nurseries, Cheshunt, for a charming bank of pot Roses, *Crimson Rambler* and *Caroline Pillar* playing a prominent part. Manchester people were again delighted to see the charming *Clematis* from Messrs. Smith & Co., Worcester, a small gold medal being unanimously awarded. The splendid *Rhododendrons* from Messrs. Waterer & Son of Bagshot were quite gorgeous, filling three parts of the long annexe. The Society's large gold medal was never more deservedly awarded.

Messrs. Barr & Sons had excellent selections of *Irises*, *Pyrethrums*, *Papavers*, and numerous herbaceous cut flowers (silver medal). The same award went to Dicksons, Ltd., Chester, for a truly handsome display on similar lines to the above, the arrangement being noted for good taste.

GUELDRES ROSES AND CATS.—Has it ever been noticed by gardeners how fond cats are of the smell of the wood and bark of the Gueldres Rose? I have three cats, and they all frequent almost daily two trees in my garden. They smell the bark, bite it, rub themselves over it, and scratch it for some minutes at a time. They do not behave in the same manner to any other tree in the garden.—J. B. C.

THE YOUNG GARDENERS' DOMAIN.

FORCING FRENCH BEANS.

I HAVE never found Beans to emit roots from the stems after they have been top-dressed, but I find they root into the fresh soil just as well as if they were potted. For in potting one must pot them deeply or leave a lanky stem protruding out of the pot, which I prefer not to do. But as to the earliness in bearing, I give preference to my top-dressed ones, although not a fortnight.—SINGLE W.

PACKING.

(Continued from page 490.)

HAVING referred (page 489) to the packing of Grapes, Peaches, and Strawberries, other kinds must not be overlooked.

PINE APPLES.—These need great care in packing; their crowns must be preserved intact. The fruit have tissue paper placed round them, and are then laid on their sides in a box on a bed of wood wool. The spaces between the fruit and the crowns are also well filled with the same material. Another way is to have a box so deep that the fruits may stand upright and the crowns be free, but if they are packed in this way they must have plenty of wood wool between them to hold them securely in position, and the lid of the box labelled, "This side up, with care."

FIGS.—These require to be packed in a single layer. The boxes are about 2½ inches deep, and lined with paper. The fruits are wrapped separately in soft Vine leaves, and laid as closely as possible together. More leaves are then used for covering the fruit.

Raspberries are packed the same as Strawberries, but for dessert and preserving, Cherries, Currants, and Gooseberries for dessert are placed in boxes about 4 inches deep, lined with Vine leaves. Plums for dessert are placed close together in shallow boxes, one layer in each, Vine leaves being used for the bottom and the top of the boxes. Apricots are packed in the same way as Peaches and Nectarines. Cape Gooseberries are placed in boxes with the husks on the fruits, nothing else being necessary if the box is well filled.

Pears and Apples for dessert are placed in shallow boxes deep enough to hold one layer, the boxes lined with paper, and the fruits packed as closely as possible. They may also be packed in boxes or hampers holding several layers. No fruit of any kind should be packed in an over-ripe state.

CUT FLOWERS.—These, like fruit, require to be packed closely to prevent displacement by shaking. For sending small quantities by post boxes made for the purpose may be obtained from nurserymen or cardboard box manufacturers. A layer of cotton wool, previously damped, is put in the box, and covered with tissue paper, the flowers then laid in, and the remaining space filled with Fern or any green foliage that is light. When sending mixed flowers away in large quantities wooden boxes are used, placing the heavy flowers at the bottom, and the lighter ones on the top, covering with the green foliage that is required to assist the flowers for decoration. Flowers which are easily bruised, such as *Gardenias*, *Camellias*, and *Malmaison Carnations*, are packed in single layers in shallow boxes.

PLANTS.—The shallow hampers, which are familiar to every gardener, are the best for packing plants in. Some plants require greater care than others, especially Orchids. If these are in bloom a piece of tissue paper is tied round each flower to prevent bruising, and the stalk fastened to a small stake. Stakes taller than the plant are then forced in the pot, and paper wrapped round so as to enclose both pot and plant. Palms and other hardier plants only require one stake, and the leaves tied to it, covering only the foliage with paper. When packing in the hampers the bottom is well covered with hay or straw. The tallest plants are placed in the centre, and the spaces between the pot filled with the same material. Strong cord is then strung across the hamper, so as to keep the plants in their places. Large stakes made of Willow, Hazel, or Ash are then stuck in the hamper at equal distance apart, and the ends drawn and fastened together at the top; mats placed round and secured, so as to prevent cold draughts reaching to the plants, completes the operation.—ELVEDEN.

TOMATO CULTURE.

(Continued from page 490.)

CONTINUING my remarks on page 490 it is necessary to refer to the diseases and insects to which Tomatoes are liable, also to the selection of varieties for home use and exhibition purposes.

DISEASES.—Most of the diseases of the Tomato may be traced to want of heat or neglected ventilation. *Cladysporium fulvum* is one of the worst affections, first showing with a few black blotches on the under side of the leaves. Careful ventilation and fire heat for keeping a circulation of dry air in the house, watering the plants in the morning when it is required, and cutting of all affected leaves, are the surest remedies and good means of prevention. *Phytophthora infestans*, the Potato disease, is seldom seen, and is more deadly, few plants growing out of it, as it attacks the stem. Throw out the plants affected, plant others, and treat as above described. *Cladysporium lycopersici* is a disease which has given us some trouble. The black spot of decay nearly always starts from the centre of the fruit where it has flowered, and spreads rapidly over the surface. A dry buoyant atmosphere is the only remedy I know, as damp is the chief cause of decay setting in.

Of insect pests the most annoying is the white fly, *Aleyrodes vaporariorum*. There are few gardens where Tomatoes are grown all the year round that escape its visitation. We find Murray's Electric vapouriser a sure exterminator. It does not injure the tenderest flower,

and is also good against red spider if it appears. Some mix sulphur and water and syringe the leaves with it. We have never been troubled with wireworm, though often using fresh loam, nor have the roots been galled from eelworm attacks.

VARIETIES.—Among the best Tomatoes are the different selections of Perfection. Having grown Suttons' Perfection, Duke of York, and Cannell's King, the first named proved a little the largest, the second the deepest in colour. Frogmore Selected is a heavy cropper of medium sized fruit, slightly ribbed. A.I. is an ideal Tomato for market—short jointed, free setting, and carrying a heavy crop of smooth medium-sized fruit. Some people complain of it, being so liable to crack. With careful selection I have obtained a variety free from cracking, and larger than the original A.I. It is useful, as in the Dublin market Tomatoes weighing half a pound bring a higher price than those only half the weight. Hathaway's Excelsior is also good, being a heavy cropper of medium size. Conference is too small with us, but an immense cropper. All the foregoing are red.

The only yellow variety grown was raised from seed saved from Frogmore Selected crossed with Perfection. The object was to raise a variety with the free-cropping qualities of Frogmore, with the size and shape of Perfection. The size is large, flavour and shape good, the colour being a rich orange yellow. It took first prizes last year at shows for a dish of yellow Tomatoes. Is it usual for yellow varieties to be raised from red?

EXHIBITION.—For exhibition there is nothing in the reds to excel the numerous selections of Perfection sent out under so many different names. Do not leave more than three fruits on a truss, cutting off all badly shaped fruits and those showing ribs. All other treatment is the same as that for general crop. If ripe too soon for a show Tomatoes will keep ten or twelve days in a dry cool room, either lying on wood wool or cut with a stalk and put in a bottle filled with water, the fruit sitting on the mouth of the bottle. It is useless trying to keep cracked fruit, as decay rapidly sets in. Do I leave too much space between the lines? Are there many grammatical errors?—W. T., Ireland.

[The spacing is quite right; grammatical errors few. If a copy is kept of articles sent the extent of revision may be perceived. It is excellent practice.]

PROPAGATION OF EUPHORBIA JACQUINIÆFLORA.

As the increase of this beautiful plant often proves difficult to the inexperienced propagator, perhaps the following remarks will not be considered superfluous. My method is simple. Tear off the young shoots from the old plants and throw them down on the Pine bed or on any shady place in the house till they stop bleeding. Sometimes I leave them twelve or twenty hours like this; then they are inserted in 4-inch pots, a sandy compost preferred, and plunged in the Pine bed under a bell-glass. In about three weeks they are well rooted and ready to be placed in 3-inch pots. A few weeks later they may be put in their final pots (I prefer a 5-inch), and the strongest plants will reach a height of 5 or 6 feet in the course of the season, producing a 9-inch wreath. At least 95 per cent. of the cuttings treated as above grow and succeed with me. Some of the last year's plants seeded, and I sowed from them on the 11th of May. To-day (the 22nd of the same month) plants are just springing through the soil, and I expect them to do as well as the cuttings; but I have never had seedlings to grow, and so cannot speak from experience on that point, but hope to do so in due time.—R. A. ANDERSON, Alnwick Castle Gardens.

FRUIT FORCING.

Figs.—*Early Forced Trees.*—After the first crops are gathered generous treatment should be accorded, so as to enable the trees to swell the second. Trees in pots require water daily, sometimes twice a day, and some nourishing food should be applied, so as to keep them in healthful vigour. Stable and cowhouse drainings must be carefully used, as they may contain little beyond urine, and require to be diluted with about six times the bulk of water. The contents of manure tanks are still more variable in strength. Sometimes the liquid is merely coloured with manurial matter, and at others it is as dark as porter. The thing is not to apply it too strong. Where these stimulants cannot be had it is a good plan to use surface dressings of fresh turf, and sprinkle some approved fertiliser over that occasionally. Planted-out trees will require water or liquid manure once or twice a week, according to the extent of the rooting area, and the roots should be mulched with rich material so as to keep an abundance of active feeders. Syringe the trees twice a day to keep red spider in check, directing the force of the water against the under side of the leaves, and letting the applications be thorough, as one good syringing is worth many sprinklings. Thin the fruit before it is the size of Walnuts, and in thinning reserve the largest fruit at the base of the shoots. Trees that are to be forced early another year should not be allowed to carry a heavy second crop, and none near the points of the shoots, or they will not be able to produce

a full first crop of Figs another season, which is of the greatest consequence.

Succession Houses.—Trees started during the first two months of the year have the fruit ripened and require a free circulation of air, warm and rather dry. Leave a little ventilation on constantly so as to prevent moisture condensing on the fruit, and increase it early to dispel any that would otherwise become deposited on the fruit through the sun heating the air more rapidly than the fruit, the cooler surface of the latter condensing the moisture in the atmosphere expanded by the sun's warmth. Take care not to wet the fruit after it commences to ripen, and afford all the light practicable. Tie in and regulate the growths by stopping and thinning, keeping them fairly thin, and not pinching where there is room, as the finest fruits are borne on extensions, especially in the first crop, spurred shoots giving good results in second crops. Do not allow any lack of water at the roots, yet give less supplies than when the fruits are swelling. If red spider attack the trees the fruit should be closely gathered and a good syringing given, which will not injure the remaining fruit, provided it is done on a fine day, so that the moisture does not remain long on the fruit.

Young Trees in Pots for Next Year's Early Forcing.—The growths of these must not be stopped much after this date, but have all the light practicable, and be kept as near the glass as possible without touching it, so as to secure sturdy, well-ripened growth, keeping this clean by syringing and the application of an approved insecticide when necessary. Afford liquid manure to insure stout, well-nourished growth. When the growth is completed, the trees may be stood outside to induce rest, but the wood must be well ripened previously, and to be of use for early forcing, it must be matured early, and never have its assimilated juices extracted by red spider or scale.

Pines.—*Potting Suckers.*—The early fruited plants as they finish will afford suckers, which should be taken in sufficient quantity to meet the demand, and be started at once. These will afford plants for fruiting about this time next year, and form a supplementary batch to those started in the spring. They require a close, rather moist pit, and a bottom heat of 85° to 90°. Pay careful attention to shading, and damp as required.

Spring-potted Suckers.—If the strongest of those potted last March are not in their fruiting pots they must not longer be kept in the small ones, as that stunts their growth and weakens them, so that they do not do well afterwards. When given their fruiting pots the plants should have a regular bottom heat of 85° to 95°, and be thoroughly well watered after potting, not giving more until the soil becomes dry, always avoiding a too wet soil, as that is not favourable to the formation of roots.

Young Stock.—The succession plants are now making rapid progress, and must not be crowded, or that will result in attenuated growth and poor shows of fruit. Afford them ample space, so as to secure a sturdy growth. Have the foliage dry before it is affected by the sun, ventilating early in the day at 75° to 80°. Watering should be attended to once a week, not giving any until it is found by examination to be needed, and then afford a thorough supply of tepid liquid manure, being careful not to apply it too strong. Syringe the plants on fine afternoons, and otherwise maintain a genial condition of the atmosphere by damping the house; but avoid a very moist atmosphere in dull weather, as it only tends to a soft growth, and that is seldom satisfactory when the weather becomes bright, often rendering shade imperative to prevent scorching. While water remains in the axils of the leaves syringing is not required, and in watering pour the water well up the plants, as they have roots in the axils of the leaves at the base, which assist their growth and make them sturdy.

Plants for Winter Fruiting.—If the strongest of the plants placed in their fruiting pots last September are not showing fruit means must be taken to effect it. Bring them together, and subject them to a resting process for a period of four to six weeks, lowering the heat at the roots to 75°, ventilating at that temperature and closing at the same, maintaining a free circulation of air about the plants in favourable weather, only employing artificial heat to prevent the temperature falling below 60° at night. Water should not be withheld; but do not give any until a plant becomes dry, and then afford a liberal supply. When the small suckers of last autumn that were wintered in 7 or 8-inch pots and shifted this spring into the fruiting pots have filled the pots with roots, they may be subjected to the same treatment as advised for the larger plants, and these will afford a successional supply of fruit.

Fruiting Plants.—Those with the crowns in close proximity to the glass will require a slight shade from powerful sun, otherwise they may become disfigured, and the fruit also is prejudiced by exposure to fierce sun. Cease syringing when the fruits commence to colour, supplying water to the roots as necessary, but avoid excessive supplies, as a wet state of the soil is apt to cause the fruit to become black in the centre. Ventilation improves the quality of the fruit, therefore admit air whenever circumstances permit, not allowing the temperature to fall below 80° in the daytime, and maintain it at 70° to 75° at night. Queen and Providence Pines started into fruit early in February will ripen this month, they coming in three weeks to a month in advance of Smooth-leaved Cayenne, Charlotte Rothschild, and similar varieties started at the same time, and under similar conditions. They afford a good successional supply, which may be still further extended by removing some of the plants with the fruit to a cooler house. These fruits are much superior in freshness and using qualities to imported, the noble specimens that are the outcome of superior cultivation completely eclipsing those produced abroad. Indeed, we are of the few in believing that even this

fruit is nowhere grown so well as in Britain, and in it could be grown to pay on the most approved and economical method of cultivation. The Providence Pine has a fine effect in table decorations, and though not equal to a Queen in quality, should be grown in limited number for its superior size and showy appearance. Enville also may be mentioned as one of the most shapely and easiest grown of Pine Apples, coming in at height of London season.

THE FLOWER GARDEN.

Subtropical Plants.—Most flower beds and borders will be filled ere this, but the efforts at beautifying a place ought not always to be confined to these details. Instead of keeping the houses crowded with plants which very few people care to see during the summer months, some of them should be transferred to sheltered nooks. Many an interesting corner might thus be rendered attractive. Strong plants of Musas, large specimens of Latanias, Chamaerops, Scaevolarias, and other comparatively hardy Palms, tall Cordylines or greenhouse Dracenas, Acacias, Cyperuses, Ficus elastica, Arundo donax, and the variegated form of Caladium esculentum, Yuccas, Aloes, and such like are all more or less well adapted for this purpose. Shade is not indispensable, but many of the plants like a moderate amount of it, and these may thus be grouped where flowering plants would fail. Planting out is not recommended, the better plan being to plunge the pots to the rim. Extra good plants are most effective quite by themselves plunged in the turf in some sheltered nook, the others being very thinly grouped in somewhat similar positions. The tallest of the Cordylines and Musas would be best disposed in shrubberies where they could be seen with only the upper part of their stems exposed. Most of them, if kept properly supplied with water, could be returned to the houses in the autumn before severe frosts damage them, and would then be available for the next season.

Greenhouse Flowering Plants.—Some of these might also be utilised for the adornment of pleasure grounds. Fuchsias invariably thrive well in the open, oftentimes after they have refused to do so under glass. If it is desired to save the plants for another year plunge the pots to the rims in the turf. Standards are very effective as "dot plants" in beds of Begonias, while these, pyramids and bushes, may also be placed in groups on the lawn by plunging the pots. If kept well supplied with water and liquid manure they will flower grandly till the autumn. Cannas are very effective in masses, and continue flowering throughout the summer. These may either be plunged or planted out. Erythrina crista galli attracts far more attention outside than it does under glass. A mass is very effective either planted out in a bed or plunged in the turf. Hedychium Gardnerianum again grows very sturdily, and flowers grandly in the open; and if plunged in pots can be moved when getting shabby, and some other plants take its place. Pyramids of Ivy-leaf Pelargoniums treated similarly to Fuchsias are very effective, and the same may be said of trained Pelargoniums generally, and also Heliotropes. Large Celosias or feathered Cockscombs plunged in the turf in July are very showy, and even the ordinary Cockscombs, turned out after they are nearly or quite fully grown, last for a long time.

Mulching Flower Beds.—During hot and dry weather there is every inducement for the watering pot and hose to be freely used, and this not always to the advantage of the plants. Very often a light watering applied in the evening is all that is needed, the soil though dry on the surface being quite moist enough underneath. Constantly drenching the ground with cold water greatly impoverishes it, and many plants do not thrive well under such conditions. A light surfacing of common salt, stirred in with a small Dutch hoe or a pointed stick, would make many soils more retentive of moisture, also proving a good manure when washed down to the roots, and ought to be tried. In most cases a mulching of either old Mushroom bed refuse, leaf soil, well decayed tanner's bark, fine peat, cocoa-nut fibre refuse, or even fine dry soil, would conserve the moisture in the beds and obviate the necessity for watering so frequently. Especially ought Tuberous Begonias, Verbenas, Fuchsias, Violas, and Calceolarias to receive this attention. First give the beds a good watering, unless fortunately a soaking rain falls opportunely, and the next morning lightly stir and level over the surface with a flat hoe, and then apply the mulch, the whole of the bed being covered with a moderate thickness of it. This mulching may not wholly do away with the necessity for watering, and should the weather continue dry and hot the soil ought to be probed occasionally, and water given when needed.

THE KITCHEN GARDEN.

Preparing Celery Trenches.—Planting in double lines in trenches 18 to 20 inches wide is a doubtful advance upon the older practice of arranging in single lines. If large "sticks" are not required the plants may be put out 6 inches to 8 inches apart, and a single trench be made to hold nearly as many as can comfortably be got into double rows. For these the trenches may be from 12 inches to 15 inches wide, and 4 feet apart from centre to centre. In the case of cold clayey soils deep trenches are a mistake. Where the position is hot and dry, a gravelly or sandy subsoil prevailing, the trenches may be made deeper, and if the Celery is addicted to bolting much earlier than is common elsewhere, owing to a deficiency of moisture at the roots after moulding up has commenced, lay a loose drainage pipe down along the bottom of the trench, with a stand-pipe at the upper or highest end connected with it. By means of this drain, water or liquid manure can be poured

down the stand-pipe and distributed along the trench simply and effectively.

Celery Beds.—Very superior early, as well as midseason and late Celery, is sometimes grown in beds raised by the addition of manure, fresh loam, and burnt refuse above the ordinary garden level. In this instance the blanching is effected by means of bandages of brown paper in sufficient quantities to exclude the light, a strip of canvas preserving the paper late in the season. The advantages of these beds are a warm root run, facilities for watering and feeding as long as need be, and immunity from slug and grub attacks.

Planting Celery.—Celery plants move best when they are not more than 6 inches high. When much taller they are bound to flag badly in either dull or bright weather, whereas sturdy plants scarcely show any signs of trouble. The plants ought always to have a good soaking of water an hour or two before moving them, and each should be cut out with a square of soil and roots, and be cleared of weeds, suckers, and small leaves. Replant firmly, follow with a good watering, and during dry, hot weather keep well supplied with water.

Celeriac.—When the early Cauliflower is cut the plants may be cleared off, the ground hoed and freed of weeds, and Celeriac be planted without any further preparation. It is not a strong leafy growth that is wanted, but rather the formation of a stout Turnip-like base, and that is why moderately rich yet firm ground is recommended. The plants ought to have been prepared in beds, ready for moving, similarly to ordinary Celery, and should be transplanted equally carefully. Dispose them quite on the level, 15 inches apart each way, well fix them in the ground, give water at the time, and occasionally during dry weather, till all are well established.

Lettuce.—Seeds of favourite varieties ought to be sown every fortnight during June and July, where the plants are to heart. The square-topped ridges between Celery trenches suit Lettuce admirably, and should be utilised for this important crop. One central row is enough for the spaces between early Celery, but two rows may be grown between the late crops. Make the soil fine to a good depth, open shallow drills, and if the soil is in the least dry water it well prior to sowing the seeds.

Beet.—Where thinning is necessary this should not long be delayed. Leaving the plants moderately close together, or 6 inches to 8 inches apart, is a preventive of coarseness; but if the fault lies in the direction of the roots being too small, leave them 9 inches apart, stirring between the rows with a Dutch hoe about once in a fortnight keeps down the weeds, prevents the ground from cracking, and conserves moisture.

Carrots.—Before the rains came the plants presented a very patchy appearance, but in all probability much seed has germinated since. This may not be to the disadvantage of the grower, as it not unfrequently happens that late sown Carrots form more desirable, if smaller, roots than those raised earlier. In any case it will soon be time to sow more seed, preferably of the stump-rooted or Horn section, with a view to having an autumn supply of tender and sweet roots to supplement late Peas. The drills may be drawn 9 inches apart, and if the soil is dry at the time be watered prior to sowing. Late Carrots are much liable to be grub eaten. Sow wood ashes lightly with the seed as a preventive. Thin main crop Carrots to a distance of 6 inches apart, allowing more space if large roots are desired. The final thinning may be done gradually, or according as young roots are required for use.

Onions.—The earlier these can be thinned out in reason the better. They draw the most readily when not more than 4 inches high. If the rows are from 10 inches to 12 inches apart thin out the plants to a distance of 4 inches apart, if large bulbs are required. The most serviceable crops are often never thinned. Dust soot freely among the plants, and do not neglect an opportunity for surface hoeing. Onions may be transplanted in showery weather.

Parsnips.—If Parsnips are transplanted let it be for the sake of appearance. There should be no undue delay in thinning out the plants where thick, eventually leaving them from 9 inches to 1 foot apart, medium sized to comparatively small roots being of more value than the coarser ones.

SWEET PEAS.—Very early and of free growth, coming into bloom profusely, were Sweet Peas at Woodhatch, the seeds being sown in long troughs several inches wide and deep. This is done early, under glass, and when the plants are stood outdoors in warm places, the boxes are well earthed-over to encourage rooting outside. Not only are the plants staked, but they are in bud. When I saw them recently outdoors they were blooming profusely, thus furnishing early a large supply of the favoured sweet perfumed flowers. Of course it is needful to give the plants an ample supply of water, and some liquid manure. It is surprising so treated how long they continue to flower. No doubt the roots find their way out of the boxes into the moulded-up soil and manure mulching. A few days after being at Reigate I saw a grand row, the plants then being fully 4 feet in height, and also flowering profusely at Gunnersbury House. Mr. Hudson sows in 8-inch pots in November, keeps the plants in a cool frame all the winter, then turns them out in a warm part of the garden into a long row, and about 15 inches apart, in the spring. Again, in this way not only wonderfully fine but very early flowers are obtained. Whilst at Woodhatch the varieties are mixed, at Gunnersbury there are but six planted in blocks of about a dozen pots each. They consist of Blanche Burpee, the finest white; Venus, soft flesh; Her Majesty, Countess of Rainor, Lady Penzance, and Firefly; really a beautiful selection. A late sowing for succession was just well up.—A. D.

THE BEE-KEEPER.

SEASONABLE NOTES.

BEE-KEEPERS whether on a large or small scale must now decide in what form they will obtain a surplus, as in districts where the bulk of the honey is obtained from field Beans, White Clover, and the Limes, the next six weeks will decide the question whether the present season will be a good one for honey production.

Prospects are decidedly good. Since my last notes the much needed rain has come; the temperature, too, being higher is all in favour of the plants making a rapid growth. Already the parched up sheep pastures, which are composed chiefly of White Clover, are progressing favourably, and will be in full bloom by the last week in June. Beans, of which there is a limited quantity grown in the district, although short on the stem, owing to the cold winds experienced this spring, are just opening their flowers. The honey obtained from field Beans is of good flavour, with a pleasant aroma, but is rather dark in colour. Bees work freely on them, and if there is a field of Beans within two miles of the apiary will disregard all other flowers in favour of them.

It is interesting to observe the ingenuity of bees in their endeavours to obtain the nectar secreted in the flowers of Beans. The tube being too long for the proboscis of the bee to reach it from the entrance, they bore a hole at the base of each bloom, and so obtain the much-coveted nectar. The humble bee is often supposed to first bore the hole, and the worker bee follows and obtains the honey, but after carefully observing the hive bees at work I am convinced they are capable of doing the whole of the work themselves.

WORKING FOR EXTRACTED HONEY.

What system is best for obtaining a large quantity of run honey of the first quality? Some bee-keepers advocate large hives with extra-sized brood chambers. Others use hives of less size, and when the queen requires more room for ovipositing some frames of brood are removed and placed over the brood nest in a top storey, the empty space being filled with frames of fully drawn out combs or foundation. This is termed the doubling system. Good results are obtained from both, but for reasons previously given I prefer the latter.

It is, however, immaterial so long as the hive is crowded and ample super room is provided for the bees to store a surplus, which should always be directly over the brood nest. If a stock has fifteen or more frames of brood in the body of the hive the same system of doubling may be carried out with advantage. By restricting the brood nest during the honey flow to ten frames, and the whole of the top storey filled with frames of brood and empty frames of fully drawn out combs, at least a fortnight before honey is coming in freely, will result in a larger surplus of run honey than can be obtained by any other means.

Colonies that have not the required number of bees may be assisted with frames of brood and adhering bees from weak stocks, for preference from those having aged queens. This should be done in the middle of a fine day, when bees are freely on the wing. It is not necessary to sprinkle them with flour, syrup, or anything else at this season, for if the frames are placed alternately with those in the hive to which they are to be united, the majority of them being young bees, no fighting will take place, and the bee-keeper will have the satisfaction of having a given number of stocks in his apiary in prime condition for obtaining full benefit from whatever flowers there may be in bloom.

Queen-excluder zinc must always be used when full-sized frames are employed as supers, otherwise the queen will not remain in the body of the hive, but will fill the frames intended for extracting purposes with brood. Shallow frames may also be used for extracting; by using them the brood nest is not interfered with. They are useful on a small scale; but after experimenting with them for several years, I have not been able to obtain as large a surplus as from the above-mentioned plan.

PREVENTION OF SWARMING.

Under the modern system of bee-keeping it is an advantage to keep the bees at work, storing honey when it is possible, instead of wasting their energies on swarming. When the majority of bees were kept in straw skeps it became a necessity for the bee-keeper to allow his bees to swarm, otherwise there would be no young queens raised, and there would be a difficulty in removing the combs, the bees being driven or, as was more often the case, destroyed. Now all this is altered, and the aim of the majority of bee-keepers is to obtain as much honey as possible without their bees being troubled with the swarming mania.

To prevent swarming it is necessary to give the bees room at the right time. It is useless doing so when queen cells are formed. If the queen cells are all removed others will at once be formed, and the bees will probably come off the first fine day. Ample space, rather in advance of their requirements, should be provided, plenty of ventilation, and shade from bright sunshine. If supers are used place a crate of empty sections under the previous one placed on the hive when it is about three parts full. The empty supers should always be placed underneath and not on the top of those partly filled. By working on the above lines very little swarming will take place, and should the weather be favourable will result in a bountiful harvest of honey instead of swarms.

COMB HONEY.

The most handy form in which to obtain comb honey is by using the 1-lb. sections, and the most useful sized crate is one holding twenty-one sections. Place them on a strong colony and cover them up warm. When the sections are about three parts filled, and the more forward sections in the middle of crate are partly sealed over, lift it off the hive, and put another crate of empty sections in its place. The crate of partly filled sections should now be placed on the top, care being taken that they fit closely. If the weather is favourable the bees will at once commence to store a surplus in the empty sections, and as the honey becomes ripened in the top sections will seal it over. When honey is coming in freely it is sometimes necessary to have three crates of twenty-one sections on a strong colony at one time. It is not necessary to use excluder zinc when sections are used.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Laburnums (F. B.).—Your specimens represent another example of the result of grafting, about which see reply to "H. C." on page 468 of our issue of May 27th, 1897.

Odontoglossum nebulosum (J. B.).—Though your flower had shrunk somewhat in travelling, it was not too far gone for its quality to be readily seen. The sepals, petals, and lip are all of very fine form, while the chocolate markings are much better than in many forms we have seen.

Temple Show Awards (C. Beckett).—So much had to be done in such little time that we were almost surprised by the R.H.S. officials supplying us with so many awards in time for publication on the night of the first day of the show. We are glad that a silver cup was granted for your exhibit, which it thoroughly well deserved.

Tomato Flowers Dropping (W. B.).—The sample was very small indeed, and considerably shrivelled by drying in the box. There did not appear to be otherwise anything the matter with the flowers. There may have been too much moisture in the atmosphere to have prevented the setting. So far as we could perceive there does not seem anything to be alarmed about. We can only suggest more liberal ventilation, leaving a little air on constantly, and enlarging the openings, before the sun acts powerfully upon the house. This should be accompanied by corresponding dryness both at the roots and in the atmosphere; then the flowers would no doubt set freely, and especially if carefully fertilised in the middle of the day. There is no harm in dusting with the anti-fungoid powder, as it will prevent attacks of fungi, and to some extent lessen the liability to damp. More air appears to be the chief want, and it ought to be secured even if artificial heat has to be resorted to.

Judging Gardens (Novice).—As you say you have never occupied the position of a judge, we think it would be very unwise to undertake the duty of adjudicating on the gardens alone. You ought not to be expected to do so, but might very well act with an experienced colleague. It is a serious thing undertaking such a duty on the part of any person who feels he does not possess the requisite qualifications, and the venture, for a venture it would be, might result in injustice to competitors, and prove damaging to the adjudicator. The process of judging is easy when a judge is capable of appraising the value of the several items he examines. It consists in determining on a standard maximum number of marks for each feature—say twelve marks, as representing the highest possible excellence. Just as the products or features fall below the standard, so must the figures representing them. It is rarely indeed that the maximum is reached, and judges who commence with it freely usually make a great mistake, as they are apt to subsequently find something better than that to which they had given the maximum before, and are then in an absurd position. With twelve marks as a standard, if you find a certain feature very good in the first garden it would be safe to give it nine, as the same feature in the next garden might be better, and worth ten; in the third it might not be so good, and only worth eight; but in the fourth it might be better than any seen before, and deserve eleven marks. So proceeding through every feature in every garden, the adding up of the figures will determine the relative merits of the whole; but practical knowledge is essential for giving exactly the right number of marks in each case, or all will be wrong at the end.

A Surprise of Garlic (A. J. S.).—You say that after a small canal was deepened several feet for the purposes of navigation, the soil that was taken out and thrown along the banks and left became covered with Garlic from seeds which, you assume, "could not have been sown by human hand, nor could have spread from plants growing in the district, as there are none for miles." Whether the plants were true Garlic or not (*Allium sativum*), we can only say that we agree the seeds were not sown by "human hand," but had been scattered in a natural manner by plants growing there at some, it may be, remote period. No one knows how long seeds will retain their vitality under favourable preservative conditions in the earth. They cannot germinate in the absence of oxygen, but when brought within its influence, also of moisture and the requisite warmth, many long-dormant unearthened seeds germinate freely. We have seen a similar instance to yours in the deepening of an ancient shallow pond, a good deal of the soil dug from below the water bed only being slightly moist. From the banks formed by this soil Foxgloves sprung up as thick as grass. We know an estate which belonged to a gentleman who was anxious to have large breadths of common Furze (*Ulex europæa*). He bought plants over and over again, but they nearly all failed to grow. The conclusion was arrived at that the land was not suitable for Furze. Subsequently, a rather deep cutting was made through it for another purpose, and on the soil thrown out Furze plants came up in thousands. A few experiments were then made, and it was found that by trenching 2 feet deep a similar result followed, and in that way clumps of Furze were established where they were wanted. Those instances came under our personal observation. Others are published of a similar nature, but still more remarkable. We cannot answer your other question; but we perhaps might if you could give the botanical name of the plant. We will make some inquiries on the subject.

Money in Mushrooms (T. D. S.).—Given full crops of Mushrooms, produced on ridges of manure, cased with soil and covered with litter, in the open air, there is no outdoor culture of anything that is so profitable, always provided the ridges are not in bearing during the time that Mushrooms are plentiful in pastures—September and early October. You do not say which edition of "Mushrooms for the Million" you have. If it is one of the early ones you should procure the latest, which is the best and most comprehensive, the price remaining the same—a shilling from booksellers, or 1s. 2d. by post. Numbers of persons have found Mushroom growing profitable, and scores of miles of ridges produce bountifully from the middle of October till the middle of June; but while several beginners succeed at the first attempt, others, as might be expected, fail. If mistakes are made as to "timing," with the consequence that the ridges are in bearing in September, the prices are too low to be profitable, while after June good crops can only be had under special conditions by experts. If the ridges are properly made of the right material, and ready for spawning about the middle of August, and good spawn is inserted, then cased, and the whole mass moist when put together, and kept so by coverings to prevent evaporation, Mushrooms will be plentiful in October, after the outdoor supply is over. July, then, is the best time for beginners to commence the collection of manure. After enough is obtained, a fortnight or three weeks must be allowed for preparation and ridging—all depending on its condition, then usually a week must pass before spawning—this depending on the heating, a few days afterwards the soil is applied, the ridges covered, and Mushrooms appear in seven or eight weeks. By commencing at the time named the manure will probably be suitable without your going to the expense of roofing the midden as you describe, but if the owner will do this by all means let him. You may perhaps have to water the mass after the shaking out is done. It may be well to have the ridge 3 feet wide and high in the first trial, and a large load of manure will be required for a yard run of ridge. All requisite details are given, and mistakes to be avoided, in the later editions of the book.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering

specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. H. K.).—1, *Phlox amœna*; 2, *Saxifraga ceratifolia*; 3, *S. altissima*; 4, *Silene maritima flore-pleno*; 5, *Saxifraga rotundifolia*; 6, *S. muscosa*. (J. B. C.).—1, *A. Spiræa*, possibly *callosa*; 4, *Lonicera sempervirens*; 5, *Limnanthes Douglasi*; the other specimens were totally insufficient. (X. Y. Z.).—1, *Pancratium caribæum*; 2, *P. fragrans*; the other specimen was *Rhamnus alpina*.

A SERIOUS COMPLAINT.

EVERY now and again comes an outcry as to the ravages of certain diseases amongst stock. That all stock is mortal is, alas! a fact too well known to need comment. We farmers expect and calculate for a certain percentage of loss, but how often the loss exceeds even the most liberal estimate. An extreme season either

of wet or drought usually leaves a mark somewhere, and if one class of stock escapes scot free another succumbs.

Some diseases are, so as to speak, under our own control, and it is from want of attention to some elementary sanitary rule that we suffer. Other complaints, again, are as the "destruction that walketh in darkness," and our men of science are nonplussed. Under most governments money is spent, and men found who with tireless energy take as their life work the study of disease, and by patient investigation work out some system of prevention or cure.

Our attention has been called lately to some cases of "milk fever," and we think it will be time well spent should we just consider this disease from one or two points of view. Milk fever we should say is decidedly an outcome of civilisation. We want to go one better than Nature, and so Nature takes her revenge. Among all the mammals of the farm the only one subject to milk fever is the cow. We have bred and selected, and selected and bred, and increased her feeding capabilities and her milk-producing qualities till we have nearly arrived at perfection. So much beef so much milk, and so greater risk of fever.

This complaint is known also as parturient apoplexy—attacks the cow shortly after or occasionally before, or at the time of parturition. Heifers with their first or second calf are practically free from this complaint—in fact, it is almost an impossibility to find a case. Every succeeding calf increases the risk, though often it will be found in a large herd that a middle-aged cow is fatally attacked before the oldest.

Of course here natural constitution is a great factor. It is the best milker that succumbs; the inferior cow is safe. Notes have been taken and observations respecting the various breeds most commonly known among us. No breed is so subject to milk fever as an English-bred Jersey or pure-bred Yorkshire—both standard types of good milk producers. Suffolk, Ayrshire, and Dutch follow in the order given. We try to breed for early maturity; we feed generously, often "not wisely but too well;" we give stimulating foods of all descriptions; we keep a good milker on year after year, instead of feeding her off and filling her place with a promising youngster.

Even respecting grass-fed cows, it must be borne in mind there is grass and grass. You do not expect to find Figs on Thistles, neither is rich grass grown on sandy poor soil. Then, again, weather is matter for consideration. The greater number of calves are dropped in the spring; yet among the fewer summer calvers you will find a much greater number of cases of milk fever. Once a cow has been down with ever so slight an attack, she always after calves at great risk. Better avoid all chances of that sort. A butcher's price is more satisfactory than a few shillings from a knacker.

Now, then, for preventive measures—forewarned is forearmed. Baring in mind that a cow of full habit of body is most liable to attack means must be taken previous to calving to keep her just in a healthy breeding state. To get at this it is wise to knock off all rich food; let what she has be plain and easily digested; give her daily exercise; see that the cow-house or box be kept clean and wholesome, ventilation not neglected, and give her occasional doses of aperient medicine.

In case of an attack remedies prescribed vary; some savants rely on strong aperient medicines, others approve of bleeding; but whatever course is adopted remember lime is of the utmost value, and measures to be successful must be prompt. Warm clothing is very desirable, and circulation in the legs should be promoted by constant rubbing with turpentine or other stimulant.

The spine, too, should be likewise rubbed, and the head kept cool by cloths dipped in water. Bear in mind that in the administering of food or medicine the greatest care should be exercised lest the liquid flow into the bronchial tubes rather than the stomach. Stimulants, too, are of advantage, wine being better than spirits, not so irritating nor so evanescent. A good "vet." should be on the place as soon as ever he can be got.

A writer of some eminence relates his experience of the management of a herd of Jerseys. The losses by milk fever had been at the rate of 20 per cent. per annum. The herd was carefully taken in hand, everything that science and closest watching could do was done, and even then the death rate was never reduced below 8 per cent. of the whole herd. Our best advice is, Do not overfeed your breeding cows, do not keep old stock, and above all use plenty of physic (salts) before calving, possibly after if the bowels need it, if not a dose of tincture of opium as a sedative.

As a proof that this is a preventible disease, we may give our own experience of the last twenty years. We keep no very big old cows, indeed never let them have more than four calves. Cake and corn bills are of much moment, that they run no risk of over-feeding. Our average is twenty calves per annum, and up to this date we have had no loss at all. The breed is Shorthorn, and some Lincolnshire Reds. A friend, who for many years has calved fifty cows per annum, has for the last three or four years had no cases whatever; before that his losses were 2 per cent., or one in fifty. Remember, too, absolute quiet after delivery must be insisted on, and the stomach kept free from over-repletion.

WORK ON THE HOME FARM.

No sooner had we completed last week's notes than rain commenced to fall, and has continued in large or small quantities every day since. The rainfall has now quite satisfied—nay, more than satisfied—present needs, and we actually have to wait a day or two for the land to become dry enough to proceed with Turnip-sowing. Once started, we shall not stay the drill until all are in. Advantage was taken of the drought to kill the twitch, and now everything is favourable for the growth of a fine crop.

The difference in the appearance of nature between this week and last is indeed remarkable. Cereal crops have grown inches in the day, whilst pastures, from being bare and brown, have put on a robe of richest green. Sheep and cattle have been quite unable to keep pace with the growth, and there seems now a prospect of keep in abundance. Had the weather remained dry much longer many meadows would have been cut, as it would have been useless to wait for more growth. The rain, however, has postponed haymaking for the present, and crops will gain in weight proportionately as they keep growing, and put off the seeding period.

Potatoes are growing fast, and require horse-hoeing and cleaning faster than they can be attended to. This work, with the putting in of the Turnips, will occupy all hands available, and keep them more than busy. Some of the Potatoes are nearly ready for earthing-up, so our hands are full indeed.

One piece of land (intended for Rape), before the rain, was like a mixture of paving stones and cricket balls. We have harrowed it to-day, and it is almost as fine as sand; in such fine condition that we shall be tempted to drill at once if time and Turnips will allow.

Cattle are doing well on growing pastures; but the flush has rather had a scouring effect on lambs, particularly on two or three-year old seeds. Maggots are becoming troublesome, and will be so whilst the weather remains damp. The ewes require careful watching, as, being lately clipped, lying on the damp ground may be the cause of downfall in the udder—a very fatal complaint, and most difficult to deal with if not taken in time.

Journal of Horticulture.

THURSDAY, JUNE 17, 1897.

EXPERIMENTAL WORK IN HORTICULTURE.

THE importance and usefulness of well devised, carefully conducted experiments cannot be too highly estimated; yet with all the good work embodied in British horticulture which has gained for our cultivators world-wide fame, anything like exhaustive experimental research has been rarely attempted. This is not because there is a lack of subjects requiring investigation, for every department teems with them; but the reason may be generally found in the length of time and expense needed to secure satisfactory results. Perhaps this neglect may be partially traceable to the old-time notion that the introduction of scientific methods is opposed to good practice. Happily this remnant of the past is steadily disappearing, and the more advanced of the present generation of horticulturists of all classes are ready to acknowledge that "Practice with Science" must give the best results in every way.

Probably no part of the horticultural community would more directly derive pecuniary benefit from the results of experimental work than nurserymen. Though few have devoted themselves consistently and continuously to any one subject, those who have done so have, in most cases, reaped an ample reward ultimately. This applies more particularly to hybridising and crossing, which have, in some instances, yielded returns in a few years; while in others a long period of waiting has been requisite. The excellent work performed by Messrs. John Laing and Sons in the development of the Tuberous Begonias, by Messrs. J. Veitch & Sons in raising hybrid Orchids, by Messrs. T. Rivers & Son in improving hardy fruits, and by the chief seed firms in securing fine types of vegetables, may be taken as examples of what can be effected by systematic and continuous efforts in cross-breeding and selection.

But that is only one section of work; there are others which demand equally careful attention, and would probably give similarly notable results if followed up. For instance, the application and comparison of artificial manures for all garden crop offers an immense field of research, and, in some cases, might yield results that would bring substantial money returns if properly applied and

developed. As regards many garden crops, it should be possible to have compounded manures, specially fitted for their respective requirements, instead of applying general mixtures which, however good in themselves, must, in many cases, be to some extent wasteful—that is, more of certain constituents are employed than are required by the particular plants for which they are used. The economic and practical value of a series of experiments dealing with manures for garden plants would be very great; but such an undertaking would have to be designed on a thoroughly scientific and practical basis to insure reliable and useful results.

Then, too, there are many cultural problems that need solution, or difficulties that have only been partially or locally mastered, and therefore require more extended observation or repetition in other districts. Much that perplexes the horticultural student can only be satisfactorily elucidated by an accumulation of accurately recorded experience from gardens in diverse soils and situations, and though the volumes of the *Journal of Horticulture*, for instance, furnish an encyclopædia of such observations; yet they would require an immense amount of labour or methodising and condensing to give the essential points in a comparable form. Thus it is that in the daily work of thousands of gardens, what may be termed desultory experiments on scores of important subjects are conducted, the observations upon which, for want of methodical arrangement and recording, are lost to all but those immediately concerned in the work, nor do they even derive the full benefit that might accrue under systematic treatment.

Gardeners certainly, in but few instances, can devote either time or labour to experimental work pure and simple; the demands of the present time are too great, and the means allowed too restricted to permit of any fanciful indulgencies in "experimenting," yet an observant man is often induced to try fresh methods in seeking to economise labour or expense, and his efforts are really practical experiments that may be perfect in themselves and only need careful noting and judging of the results to be of sound service. Too often, however, such experiments are defective, and in the very way that a scientific man would be most likely to avoid, and it is there that the union of practice with science becomes important. It unfortunately happens that it is difficult to bring about this union, for there is much too frequently a mutual distrust that is in direct opposition to all progress. The practical man is apt to look askance at the work of the scientific man because he believes it to be purely theoretical, and the latter falls into a similar mistake in attaching too little importance to the working experience of years which has at least been able to show many cultural successes.

It is scarcely possible to imagine a better combination for experimental work in horticulture than that of a gentleman with a mind trained in scientific research, and an educated cultivator who has been similarly trained in his calling, and whose powers of observation are naturally acute. Such a union of forces is possible to thousands of amateurs who wish to render their gardens something more than mere sources of supply to the kitchen. The interest which can be obtained from experimental work even on the smallest scale is wonderful and never-ending, and it is difficult to imagine any more delightful form of recreation to the thoughtful man engaged in an exacting profession or the rush of a business. Many most useful experimental stations could be thus formed, and all that would be required would be methodical observation in a general basis. Why should not such observers, properly accredited, be placed in communication with the Royal Horticultural Society as a centre, in the same way that the Royal Meteorological Society receives observations from different stations throughout the country? The material collected in this way would furnish most valuable information as time passed, and coming from so many different places and soils would render the facts of much greater utility than if from one or two stations only. Even though each individual observer had to publish his own results, such experiments are greatly needed, and a few remarks will therefore be offered on procedure in a future issue.—OBSERVER.

EARLY CHINESE PRIMULAS.

THE Chinese Primula is regarded as an exceptionally useful decorative plant because of its freedom in blooming during the winter, when, with the exception of a few popular early bulbs, there are few flowers to give a display. In order, however, that Primulas may bloom in the early part of the winter, it is necessary that strong plants be secured from early sowings. These should be grown under favourable conditions, when they may be relied upon to give satisfaction. Pots or pans of seedlings from the early sowings ought now to be receiving cool treatment, either on a shelf near the glass in a greenhouse, or similarly situated in a cold frame. This renders them sturdy by inducing a steady growth.

Before the seedlings begin to crowd each other, transplanting ought to take place. If this is carried out while the seedlings are yet small, they are best placed about 2 inches apart in pans or boxes, but the larger examples that have remained a longer time in the receptacles in which they germinated, may with advantage be placed direct in small pots; $2\frac{1}{2}$ -inch size pots are usually the most suitable, but seedlings that have germinated thinly and since grown freely, may probably have developed sufficient roots to occupy larger sizes at the first potting.

The soil must be light, open, and fairly rich, so as to encourage the formation of abundance of fibrous rootlets. Loam, leaf soil, with silver sand and crushed charcoal, form a good compost. Drain the pots or pans well, and use the compost in a moist, sweet, friable state, so that heavy watering will not be necessary at first. Gently sprinkling the plants and soil will afford the refreshment and moisture demanded.

Shade from bright, hot sunshine is absolutely necessary, not only to prevent excessive evaporation from the soil, but to guard the leaves against scorching. Shade, moisture, warmth, and a genial atmosphere are the prime essentials for inducing active growth. To these conditions must be added the gradual admission of air as the strength of the plants increases. Let the plants have all the light possible other than fierce sunshine.

It is well to move the sturdy young plants from pans or boxes at the earliest moment after the leaves encroach on each other's space. Pot singly in similar compost to that used previously. For the majority 3-inch pots will be large enough. They must be clean and efficiently drained. In potting sink the plant low, but keep the growing point well visible. Rootlets will be emitted from the stem below the bottom leaves. These, of course, are of great advantage in strengthening and assisting growth. Place the pots in a cool frame, standing them on a moist base of ashes not far from the glass. Maintain a moist atmosphere by sprinkling the plants lightly in the afternoons of warm days, when the shading employed in screening them from the midday sun is taken off. Moistens also the unoccupied spaces (if any) in the frame. For the first week or ten days the lights may be kept closed. Afterwards admit air gradually.

Watering is no less an important detail than the preceding. As the roots take possession of the soil and ramify in it towards the sides of the pots, the soil becomes quickly dried on many occasions, rendering frequent attention necessary. Small pots in hot weather should be examined at least three times daily, ascertaining the condition of each individual plant before applying water. Indiscriminate watering is an evil. It is apt to sour the soil, especially of those plants which receive more than they want. Water warmed by the sun or taken out of a greenhouse tank is preferable to freshly drawn cold water.

Unless larger plants are required the next potting may be final, if the plants are strong enough to be shifted into 5 or 6-inch sizes. As soon as the small pots are well furnished with healthy fibrous roots the potting may take place. The roots and soil must be thoroughly moist when the move is carried out; therefore sometime previously well water the plants. The soil for potting must be good fibrous loam two parts, sweet flaky leaf soil one part, decomposed manure half a part, a quarter part coarse silver sand, and the same quantity of crushed charcoal. The whole must be well intermixed by turning over several times, and bringing it to a moist state, if dry, by sprinkling with tepid water.

The drainage in the pots must be well placed, and covered with a layer of turfy fibre, to prevent the soil being washed down among it. When the plants are turned out of the small pots, pick away the crocks from the base, and place them in suitable-sized pots before introducing any soil. This admits of the plant being low enough, so that any bare stem visible can be covered with soil, and the potting be more firmly carried out. If too low, soil may be introduced to raise it before admitting the plant. At this shift there should usually be a space of an inch all round the ball. As the soil is filled in round, shake it down level, and make it somewhat firm with a potting stick. It is quite important that it should be as firm as the

old ball. Soil, however, of a retentive character ought not to be rammed hard.

The details of management after potting may be on similar lines to those advised for the younger plants. A good watering will be required in a few days after potting, then wait before giving more, or until the surface dries. Keep, however, the surroundings moist, and for the first week limit the supply of air. Shade during the middle of the day, but at other periods allow plenty of light, the plants having a position near the glass. Growth will soon proceed freely again, when air may be gradually and regularly given, finally admitting a supply on favourable nights as well as days.—E. D. S.

VEGETABLES FOR HOME AND EXHIBITION.

ONE of the chief difficulties a writer has to encounter in dealing with such a theme as this is to say something entirely new. The best thing is not to try to do so, but to say something that is believed to be true. The first truth to be impressed on the minds of the young especially is that the production of a continual supply of vegetables is an indispensable part of a gardener's duty. It follows, then, that young gardeners should pay all possible attention to this phase of their occupation, and strive to become masters of the art of vegetable culture. Yet it is possible to point to men who have passed from one establishment to another during their years of probation, and then taken head gardener's positions without having done a week's work in the vegetable department, which they really know very little about.

This is not always the fault of young men. They are engaged for the houses, and the labourers do the kitchen garden work. The only opportunity the former have of becoming conversant with this all-important branch of their calling is by going round in the evening and taking notes of the operations. Something may be learnt in this way 'tis true, but the use of the spade teaches lessons that are rarely forgotten, and taking active part in the work gives an emphasis that cannot be obtained by precept. Many a young gardener goes through the routine of decorating, propagating, plant and fruit growing without being able to say that he has passed a similar period in digging and trenching, sowing, and planting, with other operations connected with the production of vegetables. No such man can call himself a gardener in the truest sense, and I would urge on all probationers the importance of obtaining sound knowledge gained by practical experience and observation on this phase of their calling, as they will in due time have to cater for the wants of the kitchen as well as the drawing-room.

A word also to head gardeners who know the logic of all this. Their experience tells them the importance of being good vegetable growers, and knowing this they will do well to remember that the young men are not only under them to fill certain offices and to perform certain duties, but also to learn that which in after life shall fit them for the positions which they, the present gardeners, will have to vacate. Bearing this in mind, they may so regulate the labour that the young men when making changes can truthfully say that they have spent a portion of their time in the kitchen garden. It is not enough for a youth to spend the first year or so of his career in the vegetable department, and then think he has learnt all there is to know. Soils and conditions vary so much that a method of cultivation which answers well in one place results in partial or entire failure in another, hence the necessity of keeping in close practical touch with the work of the kitchen garden.

Gardeners nowadays have to reach a high standard in vegetable culture. Those who grow for sale know that it is only first-class produce which is remunerative, and those whose duty it is to supply the wants of private families know that employers want quality and a regular supply, therefore they must make themselves conversant with the best varieties, and work generally on lines that will give the best results. In variety there is a danger of confusion, as there seems no limit to the named forms of each kind of vegetables, and often there is a difficulty in discriminating between them. Whether there are not many of these too much alike to be classed as distinct varieties is a matter for argument; and here, again, a man must rely chiefly on his own experience, and he will not be long in removing the chaff from the wheat.

The latter remarks are also applicable to the cultivation of vegetables for exhibition. The best varieties must be obtained, in order to be able to compete with any hope of success. Comparatively speaking, gardeners who grow vegetables for show are limited, and though such names as Waite, Wilkins, Pope, Beckett, and Foster flash across one's mind, these are but few when we think of all the kitchen gardens in the country. Perhaps vegetables are not made such an important feature at our great shows as they deserve,

though it is gratifying to note that the interest is a growing one. The promoters of horticultural shows have to cater for the public, and it is only natural that the average visitor who is not a gardener will see more to attract him in a beautiful group of Orchids or other flowers than he will in a collection of vegetables, no matter how good. At many important shows the competition is chiefly for prizes offered by seedsmen, and those who have seen the collections that have vied with each other for the substantial prizes offered by Messrs. Sutton & Sons at the Reading Show know to what a pitch of excellence vegetables can be grown, and with what taste they may be displayed on the exhibition table.

It is at village and cottagers' shows that vegetables are most appreciated. They form the chief items at such exhibitions, and here, too, we may notice signs of growing interest and marked improvement. A great drawback in the past has been the method, or rather want of method, in the judging of vegetables, and this has been felt at shows of all kinds. For years a conflict has been going on between size *versus* quality, and though the latter is now gaining the upper hand there are judges left of a very old school who still believe that a vegetable to win a prize must necessarily be large, and therefore other points are sacrificed in favour of this. Confusion has been, and still is to some extent, the result, and exhibitors are often, in the absence of any rules to guide them, at a loss to know whether their largest or medium-sized examples are most likely to find favour in the eyes of the judges. I say in the absence of any rules, and here I must apologise to the Royal Horticultural Society, whose really excellent code was drawn up and published to meet such cases as this. To use the words of a proverb, everybody knows the ease with which a horse may be led to the water, and everybody is aware of the impossibility of making him drink unless he is disposed to do so. So it is with judging rules. They may be published, but there is a certain amount of conservatism in human nature which leads a man to believe that a rule he has followed for a long time is the right one; and I am afraid, in spite of the code of rules, the man who has favoured size for so long will favour size so long as he adjudicates, and it is only time that will put the judging of vegetables on such a basis that the exhibitor shall know exactly the ends at which he must aim.

It is only fair to say that this difference of opinion is more noticeable in small than large shows. Not long ago I asked a judge at a rural exhibition why he had given the first prize to a pair of huge, coarse Cabbages and passed over others of far superior quality. By way of explanation, he simply answered, "Well, it's a cottagers' show, you know," and looked greatly astonished when I failed to see the logic of the argument, if such it can be called. The judge referred to is one of a class still common, who seem to hold the opinion that the first consideration of the small grower is to get something big in the way of vegetables, and all other qualities are of minor importance. Size, consistent with high quality, is another matter, and the sooner this is more fully understood and acted on the better it will be for all concerned.

Next to producing the best vegetables the most important point is that of displaying them to the best advantage on the show table. They should be so arranged as to be pleasing to the eye, though the medium must be aimed at. Many exhibitors weaken their chances by the injudicious use of garnishing material, and in trying to make their collections look well overdo it and spoil the effect entirely. Here again I offer a word to young gardeners when visiting shows not to spend all their time among the fruit and flowers, but to give an adequate portion of it to the vegetable department, and take notice of the good points and the defects, the methods of arrangement, and so forth. The splendid examples that are shown by such men as I have named are not attained without judgment and study, hard work and constant attention, and we must remember that it is one thing to stand before a show table and criticise, and quite another to produce vegetables of equal merit. I hope in subsequent articles to give notes on the cultivation of different kinds of vegetables for kitchen and show table that may be of interest and assistance to some readers of the *Journal of Horticulture*.—A GROWER AND JUDGE.

To be continued.)

HELIOtropES.—Although fifty years ago Heliotropes were bedding plants, yet there was but one—and that a light flowered, somewhat coarse growing variety—in cultivation. Now we have many varieties, strong and dwarf, the latter being considerably used either for massing or as carpet plants beneath white Fuchsias, variegated Abutilons, or standard Ivy-leaf Pelargoniums, and their rich perfume is greatly enjoyed. Of dark hues, Comtesse de Mortemarte, President Garfield, and Jeanne Daudier are of the best; and of lighter ones White Lady and Paul Pfitzer are excellent. This variety in colour and habit enables the Heliotrope to be more largely grown in gardens or as pot plants, for so grown they are valued for decorative purposes.—A.

WANDERINGS UPON WHEELS.

A LONG anticipated trip with a daughter, upon bicycles, which was originally intended to include several places of horticultural and especially rosarian interest, had unfortunately to be postponed two or three times, with the usual result that several localities had to be omitted altogether. Mr. Lindsell was unable to receive us at Hitchin; Mr. Mawley was also not at home at Berkhamsted; Mr. George Paul wrote that he was receiving, on the day suggested, The Scribe and Mrs. Ancient Briton (these are not exactly the names he gave to his guests), but that his son would welcome us; and yet, entirely through the writer's fault, we did not go even there after all.

We started soon after midday from Bedford, on May 31st, our destination being some seven miles south of Dunstable. We did not go the nearest way, as I wished to visit the grand old rectory garden of my childhood, not far from the scene of Mr. Empson's horticultural triumphs, which I should like to have glanced at. The old garden was but little changed: many of the trees looked pretty nearly the same, as far as I could judge, as they did fifty years ago. Even the Asparagus bed, in the old place, looked exactly as it used to, with apparently the same Raspberries growing beside it. One tree, a yellow Chestnut, had grown considerably, and become quite a fine specimen. I was told it was one of the biggest in the county. It must be a very slow-growing variety, for it certainly altered very little, in my recollection, during my childhood and early manhood.

Away again south, with little worthy of notice save our continued blessings on the Beds County Council, or whoever is responsible for the truly magnificent roads of the county, till Dunstable is reached. What a pity so much of those fine downs is under plough. Surely that uncanny-looking chalk soil would bear sweet short grass, with greater advantage to the pocket as well as to the eye, than ordinary farm crops in these dry seasons. I was amused, on leaving Dunstable, where we had to ask our way, to be told that after taking a certain turn, we were to "bear a little to the left." This was warmly impressed on us as a parting injunction. Somehow or other this tickled me much, for if there had been a turning to the left (and as a matter of fact there was not one) we must either take it or leave it, and I could not think where the "little" came in. The lady solved the matter by persistently keeping on the left side of the road, but it did not seem to me (we were now in Bucks) any better than the other.

That night we admired a vicarage garden at our resting-place, reduced from chaos to admirable order by the vicar and his sister with the help of an occasional boy, and I told them of two or three of the principal faults of the ordinary groom and gardener. One is that he will sow everything too thickly, and not thin early enough. Another is that on putting out plants, say Strawberries or the Cabbage tribe, he will dig his ground and plant as he digs. The truth that such things like to be planted in firm hard ground is, I venture to say, very generally unknown to the ordinary cottage gardener.

Another thing I mentioned is that, a few days before, I found a man watering his trees. It does not matter whether they were Apple or Rose trees, or whether it was water or liquid manure. He was putting it, a few inches wide only, just round the stems. Touching him upon the shoulder I said, "If your wife were going to give you a cup of tea, is this the end of your arm she would put it to?" "No." "Why not?" "Because I catch hold with the other end." "Just so," I said; "and yet you are pushing their tea against the underground shoulders instead of the hands of your trees. You know, if you come to think, that the trees catch hold of nutriment at the end of the roots instead of the bottom of the stems." He was digging in a thoughtful manner, with his head on one side, when I left him. And yes! I do verily believe he was thinking.

I found next day, when we started about one o'clock, that it was further to Hemel Hempstead than I had anticipated; moreover the wheels of my chariot, for some reason that was not assuageable by oil, ran heavily, and the road was steep and bad. We went right through Lord Brownlow's beautiful park at Ashridge, but the only thing I saw they propagated in quantity was pheasants. Thence by an indifferent road to Hemel Hempstead, and on by a really bad one to St. Albans. Here whatever mysterious nutriment the iron steed wanted was found at a cycle shop, and grateful tea refreshed the travellers. A good road and easy going wheels to Hatfield, whence we skirted the park for some distance without getting a glimpse of it, and so nine long lonely miles to Hertford. A short rest, and on again; a grand

road to Ware, and thence, in the cool of the evening, nine more miles speedily rattled off northward on the old North Road to our destination for the night.

Next morning I was a bit tired, the first seventeen miles on a stiff machine of the day before accounting for it, the lady being much the fresher of the two. We had passed through a swarm of May-flies on nearing the trout stream the day before. And a day by the river seemed altogether more congenial than another journey. Moreover, Cheshunt would keep, but a rise of May-fly will not. So I telegraphed to Mr. Paul. And the day at Cheshunt that I have promised myself for years has still to come off.

On the Thursday we started early, and rode to Bishop's Stortford, thence by train to Braintree, and then rode for home. A good, but very straight and monotonous, road it is through Coggeshall to Colchester, with nothing worthy of notice but some splendid fields of Trifolium. We arrived about twelve o'clock at the house of Mr. Orpen, West Bergholt, who is now very well known and most justly feared as a competitor in any amateur Rose class.

On entering his garden one of the first things I saw—a gracious compliment from my host—was a man vigorously and skilfully wielding, with due appreciation, a Sproughton hoe. Mr. Orpen then showed me a tool of his own devising for stirring the ground; two prongs or tines at the back of an ordinary field hoe, and at right angles to the handle for pulling through the ground, and thus "cultivating" it after the manner of a steam cultivator just as the Sproughton hoe is, after all, only a modified duplex form of the horse hoe.

The first Rose to catch my sight was a splendid specimen of Fortune's Yellow on a south wall. The plant itself was just in its prime, about six years old, covered with unusually good flowers, just at their best, and yet full of growth. There was a great deal of variation in the colour of the blooms, and they were rather differently shaped from those on older and less vigorous plants, being most decorative and handsome even when fully expanded. Mr. Cecil Cant tells me there is an increasing demand for this lovely old Rose, but that he still has a good many complaints of its failing to bloom in some seasons. He thinks it requires a warm autumn to ripen the wood, but Mr. Orpen's certainly did not have a good autumn last year, and a plant on a house in Sproughton never fails to bloom well. It is a Rose that everyone who has room on a south wall should try; and one of its great advantages is that it is very early, and always blooms in May.

Mr. Orpen's Rose plants, and especially his Teas, were of course of great interest to me. They seemed backward, but so, I suppose, are everybody's. The growth was not excessively strong, but I know that the relative positions of growth to bloom are very different at Colchester to what they are at Sproughton. There is something in the soil congenial to grand blooms—is it potash?

His Teas were not so hard pruned as mine, but he suffers less from frost, having a valley beneath him for the cold to "fall into." The number of plants did not seem to be great, but where every one is good, and a weakly one is not tolerated but at once removed, such a large number is not necessary. That Mr. Orpen is a wonderful exhibitor I had known for some time. I am now also prepared to say that I think he is a very good cultivator of Roses.

Poppies, 9 inches across; Sweet Peas very forward, having been raised in pots or boxes; and a good many Irises; besides some extremely healthy-looking fruit trees, are the other features that I particularly remember. Mrs. Orpen is very fond of Irises, and was disappointed that my taste has not yet been educated up to appreciating the "greenery-gallery" tints of some of her favourites.

Then to a welcome lunch, the rooms decorated with Mrs. Orpen's well-known skill and taste, and certain decorations, again showing the graceful courtesy of my host and hostess, being not obtruded on my notice. There were three or four very handsome silver cups and pieces of plate, two of which had graced my sideboard not very long ago. One of these I do not expect to handle again. We will talk about the other a few weeks hence.

And so we remounted our steeds, past Mr. Frank Cant's, where there was no time to linger, and on to the veteran's at Myland Lodge. I was very sorry to find him (Mr. B. R. Cant) in much enfeebled health, and not able to go far among his Roses. Cut-back H.P.'s were beginning to show colour, and looked well; a few Teas were out by the walls, but we had not really time to see anything but a few new Roses under glass. The three showing

best were all Hybrid Teas, and all from Pernet-Ducher—Madame Cadeau Ramey, Ferdinand Batel, and Souvenir du President Carnot, which last was only new to me. The first-named of these three impressed me most, but it requires a thorough knowledge of the standard of perfection attainable by grafted plants under glass to judge of their comparative merits as outdoor plants.

And then, after a grateful cup of tea, for the pleasant ride of seventeen miles home: a little marred by one of my pedals coming hopelessly off halfway, and necessitating the somewhat lame conclusion of riding the last eight miles home on one leg, but a very enjoyable trip all the same.—W. R. RAILLEM.

PRIMULA TRAILLI.

IN your note of 29th April, page 361, on the award of merit to *Primula Trailli*, shown by me at the Drill Hall on 27th April, you say, "The flowers of this rare *Primula* are borne on footstalks about 9 inches in length." As a question has been raised in some of your contemporaries as to its being closely allied to *P. Munroi* and *P. involucrata* I send you a photograph to show its much larger growth. I took the measurements carefully. Breadth of plant, $11\frac{3}{4}$ inches; height of tallest stem, 16 inches; length of leaf, $6\frac{1}{2}$ inches; expanded part of this, 3 inches; width of this last, $1\frac{1}{8}$ inch. It had ten flower stems. The plant was grown in a cold frame, and when the light was on placed close to it, so as not to be drawn up.

I received the seed about two years ago from a friend (a good botanist) in the Himalayas, with injunctions to be careful with it, as the plant had not been flowered in this country. He described it as *Primula Trailli* (Watt), Himalayas, 17,000 feet. I think that with some points of resemblance to *P. Munroi* and *P. involucrata*, notably in its very sweet smell, it is essentially distinct, and a new Primrose that will be a valuable addition to the hardy flower garden. This note would have been sent earlier, but I had to wait for the photographs.—GEORGE F. WILSON.

[We are much obliged to Mr. Wilson for the information he has furnished, and for the photograph from which the illustration (fig. 99) is reproduced.]

WALKS.

WE have decked our much-praised island home, the Bonnie Britain, with many fair gardens, the premier emblems of civilisation. To enjoy our beautiful scenery, we trace out certain tracks upon which we are led to enchanting nooks or gay fairyland spots of waterfalls and wet herbage. Past these, to calm, cool meadows, and still quiet waters; now changing a gravel-laid track for soft green sward, anon a sandstone-coated, serpent-like trail, among shady woods, or more open groups of graceful trees and flowering shrubs, planning all on the principles of utility and purpose.

Walks, where'er they go, must have an apparent purpose; no unneeded detours or meaningless sweeps on open surface. Reasons must be apparent for divergences or curves in walks. To conceal the extent of limited grounds, ingenuity in the grouping of trees and shrubs, or in raising and mantling a mound, bower, rootery, rockery or other object, is desirable, and winding our paths between and among these, in easy flows, are items of landscape gardening upon which much has been said and depends. Under circumstances, then, it may behove us to "make" obstacles in our path's course if they do not naturally exist.

We do not purpose mentioning the general routes of walks between the mansion's entrances and the scenes of interest about, for all are surely acquainted with the prevailing adoptions. The more formal walks embrace the circuit of the house, its terraces, if there be any, and the formal flower garden and fore-work of pleasure grounds. Briefly let us record a few observations on the making of walks, and their fitness to surroundings. According to the extent of the demesne and their positions their breadths vary; 7 or 8 feet is frequently suitable, but "circumstances alter cases."

Properly made walks ought to have a solid dry base, drained in all cases, except on gravelly lands, with a foot or so of graded stones, surfaced finely, and rolled hard. Thus—1 foot depth of material is removed from the staked-out breadth, the foundation secured hard and dry—for the foundation is the road—made convex with side drains as required. Place on the hardened base

4 inches of well-packed large stones, and about 8 inches of smaller ones, finishing with a raised centre (1 inch rise per 6 feet breadth) with pit or other gravel, and some binding material; soak and roll the now-completed walk till it is smooth and hard.

Various surfacings are employed other than gravel, such as asphalt or a dressing of coal tar, heavily sprinkled before it sets with yellow Derbyshire spar, white "chuckies," or quartz chips, mayhap red or yellow sandstone, rolling firmly and clean. Such walks are at all times pleasant, always smooth and free from weeds. The best of gravel walks become rough in continued dry weather, at which time to walk on them is not a pleasure, but a punishment.

The colour of walks is another consideration. Red and yellow are warm colours; grey, and it may be white, are cold in appearance. Grey river gravel harmonises with grey buildings, and is much used for pleasure grounds and by lakes. Woodland walks should match the soil in colour. Dazzling and glassy hues we banish. Recently I learned of a novelty (to me) in "elastic" walks, recommended for flower gardens. Twelve inches of soil is

FIG. 99.—PRIMULA TRAILLI.

removed; 4 inches of packed small stones are placed on the drained foundation, above which 8 inches of peat or moss (sphagnum) is trodden as firmly as possible. The moss is covered with a layer of twice burned engine ashes (grey colour), rolling this till it cakes hard. This is said to form a durable elastic path.

Ash walks may properly be used in the working parts of the kitchen garden. If they run next to walls slope them slightly to the outer edge. To properly enjoy park and outland strolls let us have grass paths or glades. Mark off the ground, dig and level it, making sure there is uniformity in depth and quality. On this sow in April grass seeds, selected; or lay down good turf, brushing fine soil or sand over it, solidifying with a heavy roller. Open side drains (screened) may be on certain soils necessary. Dressings of soot and fine soil aid these grass walks when they deteriorate. Stone laid walks have not come within my notice; will some fellow writer tablet his experience with these? It is well to make walks thoroughly at the outset.

We need not compare ill-made and well-made walks. Evenness, with depth and hardness throughout, is highly necessary.

Weeds ought never to be suffered. Any weed-killer lotion we have tried has been highly efficacious. Salt distributed fairly over the weeds or mosses means destruction. Hand-weeding is preferable to hoeing. With diligent eyes be alert towards repairs, being careful to firm the mended parts. Nothing adds so much to the enjoyment of gardens and pleasure grounds, as do, what we do not always find, but ought to have—namely, feet-comforting walks.—A YOUNG SCOT.

ROSE SHOW FIXTURES FOR 1897.

- June 18th (Friday).—Portsmouth (N.R.S.).
 „ 23rd (Wednesday).—Richmond, Surrey.
 „ 24th (Thursday).—Colchester.
 „ 25th (Friday).—Maidstone.
 „ 26th (Saturday).—Windsor and Dorking.
 „ 29th (Tuesday).—Canterbury, Hereford, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon, Ealing, Farnham, and Reading.
 July 1st (Thursday).—Eltham.
 „ 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 6th (Tuesday).—Diss.
 „ 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
 „ 8th (Thursday).—Bath, Bedford, Farnham, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.
 „ 10th (Saturday).—Manchester.
 „ 13th (Tuesday).—Wolverhampton.†
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 17th (Saturday).—New Brighton.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.
 „ 28th (Wednesday).—Chester.*
 „ 31st (Saturday).—Liverpool.*

* Shows lasting two days. † Shows lasting three days.

COMMENTS AND IMPRESSIONS—MEDALS AND PRIZES.

THE numerous schedules that now remind us of the approaching shows bring forward a subject that has often been discussed by committees, but never definitely decided—namely, the relative value to exhibitors of medals or cups and money prizes. There is so much to be said on both sides of the question that it is not likely it ever will be settled, and the best way out of the difficulty appears to have been taken by most societies in offering both medals and money in certain classes. I was present, a short time since, at a meeting of a provincial society where the matter was brought forward and vigorously discussed, especially by two of the members, whom we will name respectively as Mr. Cups and Mr. Cash. The former, a very successful and thorough amateur grower and celebrated athlete, stoutly maintained that competition for money prizes was utterly opposed to the true spirit of amateurism. He contended that there should be sufficient interest in, and love for, the Rose to insure abundance of exhibits without the inducement of money. Cups and medals he considered to possess ten times their intrinsic value, and he referred to the pride he felt in the array of such substantial rewards that he was able to show to his friends, and which served as so many mementoes of pleasant days and hard-earned successes. “Mere money prizes,” he concluded, “would never have brought one iota of the satisfaction cups and medals had yielded, and all societies ought to encourage a similar spirit by offering more prizes of that kind rather than pander to the ‘money grabbing’ propensity that proved so detrimental to the true spirit of horticultural competition.”

Mr. Cash, in reply, congratulated his friend upon being in that happy position which enables a man to disregard such trifles as the expenses attendant upon exhibiting. He thought, however, that there were many other equally ardent lovers of the Rose, and equally desirous of extending a general interest in it, but who unfortunately had not such full purses that they could meet demands of this nature without the assistance which he contended societies should always render. The majority of such prizes at local shows rarely provided for little more than the average expenses of the exhibitors, and he stated that having kept an accurate record of all expenses and prizes won in ten years he found after a fairly successful career there was a balance in his favour of 5s. He thought that no man could be accused of “money-grabbing” with such a record, which he thought would correspond to that of many others.

The contention was continued at some length, with the result that the Committee decided to do precisely what others have done—namely, to offer both medals and money prizes in the chief classes, because it is a compromise that appeals to the good sense and experience of the majority. It is undoubtedly a great question how far exhibiting pays even the most successful. Trade growers it is understood look for other than direct returns, although when they have so many thousand plants to cut from it is doubtful if they could sell the flowers to such advantage. To the amateur and gardener, however, it is chiefly a matter of reputation, and the number who turn to exhibiting as a source of gain alone is so small that they need not be reckoned with at all, for they generally find a large share of disappointment if they have not the love of the cause which animates the true gardener, from peers and parsons downwards.

It is often a subject of deep regret to me to hear exhibiting decried, because I know by long experience what an immense stimulus and encouragement it gives to many a worthy man. A valued friend, whom we will call “Lady Cecily,” some time ago said, in the course of conversation on this subject, that she would not allow her gardener to exhibit Roses or anything else, because she thought it would waste a lot of time, and that he would be devoting too much attention to what he wished to show to the neglect of other matters. Happily I was able to point out several instances in the district where this restriction was not imposed, and yet the gardens were admirably kept in every department and at no greater cost. Further, by showing how closely a gardener is wedded to his calling, how few pleasures he has outside his duties, and how small his earnings are compared with the knowledge, experience, and time his occupation demands, I induced her ladyship to allow her gardener the privilege of exhibiting, and the result is explained in the following extract from a recent letter: “I am quite delighted with the improvements Brown has carried out in the gardens this year, and we are becoming greatly interested in his exploits at the shows; he was very successful last year, and the Roses are very promising for the present season. I am sure you were right about the exhibiting, for Brown has been much more energetic since I allowed him to measure his strength against our neighbours, and I am thoroughly satisfied in every way.”

The medal question brought to my mind an episode concerning a beautiful Rose which may be said to be peculiarly appropriate to the present year—i.e., Her Majesty, which ought to be shown in its best form for the sake of its name. I was walking through the exhibition at South Kensington when the late Mr. Bennett of “Pedigree Rose” fame came up with a particularly brilliant expression on his face. “You look happy, Mr. Bennett,” said I. “Is the world using you well?” “Happy, my dear sir,” said he in an excited tone, “I have never been so happy in all my life. I have just been awarded a gold medal for Her Majesty. Think of that—a gold medal! Why, I would sooner have that than a present of £100.” How true that was anyone who knew Mr. Bennett will realise, for he possessed an enthusiasm which carried him outside all petty consideration of £ s. d.

By the way, what an interesting exhibit could be made of the Roses which have been brought out during the Queen’s long reign, though I imagine it would be difficult to find many of those raised in the earlier years. I have a copy of the “Rose Fanciers’ Manual,” by Mrs. Gore, published in 1838, the year after the Queen’s accession to the throne, and it is surprising how few of the varieties therein described or mentioned (over 1600) are now known to cultivators. Gloria Mundi and York-and-Lancaster are the two most notable of the older varieties, while Lamarque has a place amongst the Noisette Roses, of which no less than ninety-three are described, as this type was even then in great favour with the French growers. It is interesting to note what Mrs. Gore says about the collection of Roses then of note. She says the finest are those of the Horticultural Society formed by Professor Lindley, of the Duke of Devonshire formed by Mr. Paxton. Mr. Sabine, whose valuable treatises on the Rose are well known, formed some years ago a collection at North Mumps, and one of the earliest and most interesting made in England was that of Charles James Fox and St. Anne’s Hill. Referring also to the Rose nurseries—Messrs. Rivers of Sawbridgeworth; Messrs. Loddiges of Hackney, “who cultivated 2500 varieties;” Messrs. Lee & Kennedy, and Messrs. Henderson of Kilburn. In noting the popularity of the Rose in France, it is said that one grower “produces annually from slips in a small forcing house 50,000 plants of five varieties.” Will any of our British firms surpass that in the present Diamond Jubilee year?—A MIDLAND ROSARIAN.

HARDY FLOWER NOTES.

WHEN spring was with us we thought there could be no more attractive time in the garden, so full was it of floral charms. Yet now that Queen Summer reigns, we think that she, too, has beauties unsurpassed. The Tulips and the Narcissi have gone, but in lieu of the bright colours of the former we have others brighter still. Great *Pæonia* flowers of imposing beauty vie in brilliancy with the fluttering Poppies, which, for a short space, unfold their fragile, crinkled petals to please us with their beauty ere they fall to the earth or are carried off by the wind. Roses, too, have come as if to show their superior beauty in comparison with the blooms, magnificent as they are, of the shrubs—the *Rhododendrons*—which are in name likened to these royal summer flowers. *Pyrethrums* decorate beds and borders with their tasselled flowers, while the *Columbines* are delightful in their forms and colours.

The older *Aquilegias* still hold their place in our favour, and are much loved and admired despite the exquisite beauty of the new hybrids. They are ubiquitous here. They nod from the tops of rockeries, swing to and fro to the wind in the borders, ornament the margin of the pool or encroach upon the gravel walks and dispute ownership with the passer-by. Like the Welsh or Wordsworth's Poppies, and others of the same family, they have become weeds in this garden, but weeds so beautiful that they cost us many a pang when they have to be ejected ignominiously from some spot reserved for other flowers. These *Columbines* are of all colours and hues; blue and brown, white, and almost black-purple, pink, and yellow. One would need a colour chart, and even with its use would find the whole list of colours and shades insufficient to describe sufficiently the hues of this old and favourite flower. Then the forms are, if not so varied, at least very numerous. Long spurs, short spurs, no spurs; single flowers, semi-double flowers, double flowers, with various differences of form, all occur. Who that has ever grown this flower could use with pleasure the words of Skelton, and say, "That thankless flower grows not in my garden?"

It is pleasant to find the old forms still appreciated by visitors to the garden, and to see them so delightfully spoken of by "The Missus" in her sketch of her northern garden in a recent issue of the *Journal*. The new hybrids grow side by side with them here, and by-and-by we may see some strange results of this association. Possibly these may be to some extent a retrograde step, undoing in some way the work of the Rev. C. Wolley-Dod, whose exquisite strain of hybrid forms is the one I have; but there will still be enough of distinct beauty among all to give the flower-lover his reward for the little pains the *Aquilegia* requires to induce it to grow.

On one rockery the Starry Daisy Bush—*Olearia* or *Eurybia stellulata*—is a mass of bloom. This counterpart of the "modest crimson-tipped flower" of Burns, from the Antipodes, instead of rising timidly from the turf like our native wilding, grows on a bush, and even near at hand is as closely set with flower as some lawns which afar off look like sheets of snow. The "crimson tip" is absent, but so Daisy-like are the blooms that the name of Daisy Bush is fitly given. It seems strange that this species is hardy here when in many places, even farther south, it cannot stand the winter.

June is a time of Lupines, too, and a yellow variety of the Tree Lupine (*L. arboreus*) is, as I write, loaded with its pretty, honey-scented spikes. What a pity it is that these Tree Lupines are not long-lived, as their effect is so fine that they are welcome everywhere. The herbaceous species and varieties are pretty too, while the annuals give many a border a needful variety of form and colour. I have not room to grow many Lupines, but would fain say a word in favour of a little more attention being paid to some little grown species seldom seen except in botanic gardens. Yet there are few to equal the forms of the best known of the herbaceous species (*L. polyphyllus*), with their long and tapering spikes ranging in colour from deep blue to white, and the pretty bicolor variety with its blue and white flowers.

A pretty *Anemone* has passed away for the year, but one would be sorry were it to pass unnoticed here. This is *A. balkana*, whose round feathery heads of seed still look well, and which grows on the level at the foot of one of the rockeries. On my return, after a few days' absence, the Balkan *Anemone* had come into flower, and at first sight its blooms were taken to be those of a glorified white Iceland Poppy, or those of a very miniature single white *Pæony*. Like those of the Poppy, they were crinkled, and far surpassed in purity and in texture the fine crinkled papers so often used. They were raised on stems about 14 inches high, and were much admired while they lasted, which, truth to tell, was too few days to make us weary of their loveliness. As the sepals fell we thought, as we often think when looking at some flowers, of the

words, "Whom the gods love die young," and bade a long farewell to the beauty of this sister of the Windflower of our woods.

More fleeting still are the flowers of the *Cistuses* and *Helianthemums*, the Rock and Sun Roses. There are few of the former to be depended upon in this climate of ours for any length of time, but the dwarfer, but no less beautiful, Sun Roses last for years on a moderately dry bank, and when June comes round open their fragile flowers to the morning sun. Of all our flowers there are few more fleeting in their beauty, so many cast their petals early in the day, and ere night the little bush, which the sunlight had beguiled into adorning itself with a garment of ephemeral beauty is unadorned once more, and so quiet and homely looking that the passer hardly deigns to glance at it. It will be found that these Sun Roses like a little more moisture than they often receive in the intensely hot and dry positions in which they are sometimes placed. Where the soil is not excessively dry the blooms are not so fugacious, and will at times last until the evening.

The perennial Peas are favourites with many, and are, as a rule, very decorative, either in the garden or as cut flowers. The several forms of *Lathyrus latifolius* show much variety of shade, none being of more value as a cut flower than the ivory like blooms of *L. l. albus*. *L. grandiflorus* is a general favourite, and, like the foregoing, is very beautiful, clambering over a hedge or trellis. I have been trying to secure some of the rarer perennial *Lathyri*, with, unfortunately, only partial success. This year I have first had the pleasure of enjoying the flowers of *L. pubescens*, which, rather unexpectedly, has survived the cold and wet of the past winter. For this plant I was indebted to Mr. W. E. Gumbleton, who has, one is sorry to hear, been unsuccessful in keeping it.

The plant was raised from seed sent from Uruguay to Mr. Gumbleton, and has been grown on a trellis against the gable of an outhouse in the garden. It appears to be of semi-shrubby habit, the flowering branches not being produced directly from the underground stem, but from the old stem above the surface. The flowers are entirely distinct in colour from the other perennial Peas generally found in gardens, and are of a fine lavender colour, the lower part of the flower being light, and the upper, or standards, darker. There are eight or nine blooms on each raceme, and these, although not so large as in some species, are very effective and pleasing in colour. The leaves and stems of this Pea are distinctly pubescent, so that the specific name is very appropriate. *L. pubescens* does not appear to be of very vigorous growth, but one must hope that it may become thoroughly established here.

Other flowers are brilliant or chastely beautiful in border or in the rock garden. By the pool the Buck or Bog Bean, *Menyanthes trifoliata*, is pleasing with its fringed, sweet-scented blossoms. On its margin the Sikkim Cowslip, *Primula sikkimensis*, hangs its pretty yellow flowers from the top of the tall stems. The Marsh Marigolds are nearly over, but the Irises are in bloom, and the picturesque-looking *Rodgersia podophylla* is also in flower. Saxifrages are still blooming away on the rockeries, their pretty flowers making the bright blooms of some of the *Dianthi*, such as *D. neglectus* and *D. alpinus*, appear even brighter than they are. *Lychnises* are bright too, and among the yellow flowers none please more than *Onosma taurica*, the Golden Drop. The creamy white variety of *Thalictrum aquilegifolium* looks graceful and attractive beside a great scarlet Eastern Poppy—a seedling I have named "Guardman" from its fine colour and tall erect habit. There are many others beautiful in flower, in foliage, or in both, which seek to claim our admiration as we pass them by. Lost in the garden's pleasures, we must not forget that it has its work too, and that, pleasant as it is to tell of its beauties, the pen must be relinquished for a time while the wants of the flowers are attended to. So we bid the reader *au revoir*.—S. ARNOTT.

PALMS IN RUSSIA.—In the Winter Palace at St. Petersburg is the Nicholas Salon, which is decorated with seventy-two Palms, averaging from 25 to 30 feet high. These stand in six rows of twelve plants each, and around each plant-tub is constructed a table at which ten persons can be comfortably seated at dinner. The Palms stand so far apart that their spreading tops do not touch, and the outline of each can be seen to advantage. The skill of the Court gardener is shown in the fact that these tubs are only 30 inches in diameter, and they cannot be enlarged, owing to the limited size of the table. As the Palms remain in the palace from January until May, they lose seven or eight leaves every year, which must be replaced by as many new ones before the following January. To bring about this growth the plants are turned out of the tubs as soon as they are taken from the palace, the roots are severely shortened with an axe, and the ball is re-tubbed in turfy loam, fertilised with bonemeal, and the Palms are then placed on a warm bed in the Palm house. Here they remain until their new leaves are developed, and at the New Year they are transported to the palace, well packed in thick coverlets as they are carried through a temperature which sometimes falls to 40° below zero.—("Garden and Forest.")

ECCENTRICITIES OF PLANTS.

THERE are some curious things that come across anyone who takes a pleasure in growing plants of an herbaceous character for which they cannot always find explanations, and in which they seem to depart from the normal condition of their kind. I have asked several persons about the cases that have come under my own observation, but they still remain a puzzle.

One of these plants is *Ornithogalum arabicum*. I have more than once found the bulbs lying dormant for a season and then starting up into growth; but this year I have had a still more remarkable experience of its eccentricity. Three years ago I potted some bulbs of it in 32's, four in a pot, but for two years they made not the slightest attempt to move. Nothing has been done to them; they have not been potted or top-dressed, or interfered with in any way. They have been in a back part of my greenhouse, and this year they are all blooming grandly; every bulb has flowered, and the number of blooms on a spike or truss varies from eleven to fourteen. They are a large size, and in every way perfect. We are so often told that when a plant has remained a long time in a pot it exhausts the soil. I should like very much to know when and how these bulbs accumulated strength to send up such strong trusses of blooms, and when were these formed in the bulbs. I am no botanist, and probably will be set down as an ignoramus, which I honestly confess that I am; yet, withal, I should be glad if anyone would solve this riddle for me.

Another plant which has been a considerable puzzle to me is one that I have of that grand showy biennial *Verbascum olympicum*. As far as one of my plants is concerned it is entirely false to its character. I have had it now for nine years, and this year it is throwing up some grand spikes of blooms. In one respect it preserves its character, for it flowers only every second year, although, as I have said, the plant has a continuous growth. It seems to me that the shoot comes up from the base of the plant, and acts as if it were a seedling, not flowering the first year, but preserving its strength for the following one. I have seen many plants of it elsewhere, but they have always been true to their character of being biennial, and what has led this one plant to adopt this abnormal course I am utterly at a loss to conceive.

I have more than once alluded to the disappointment that that pretty little *Calla*, "Little Gem," has caused me. I had it six or seven years ago, when it flowered, but I have never been able to get it to flower again; it grew well enough, but refused to flower. Last autumn, however, I thought I would adopt a new course of proceeding with it. I dried the plant off completely, which I am in the habit of doing with many of my bulbs, and on repotting I took away all the slender growths, and only potted the stronger ones. This plan was entirely successful, and I have had some nice flowers of it this spring. This was the more gratifying to me, because when I wrote to the firm who kindly supplied me with the plant I told them I could not get it to flower; they told me they were surprised at it, for they had no difficulty, and that they would send me a plant to show how free it was. This was very kind of them, but, alas! when the plant arrived it was not "Little Gem," but a form that I have had from another firm, and which, I believe, is called "Compacta Nana," which is midway between Little Gem and the ordinary form. Of course, I thought then that all Little Gems would in process of time alter into this intermediate form, and I was, therefore, the more glad to find that I was mistaken, and that Little Gem remains Little Gem still. The beautiful yellow forms of the common *Calla Pentlandi* and *Elliotiana* are, I fear, beyond me. I had a plant of the former, but learned too late that it required more heat than I can give it, and consequently it rotted away, and I have been obliged to abandon the attempt to cultivate it.—D., Deal.

THE INFLUENCE OF MICROBIC LIFE IN THE NUTRITION OF PLANTS.

AMONG the results of the evolution of the microscope and the perfecting its higher powers during the past quarter of a century, the most interesting and far reaching have been the discovery and investigation of the infinitely minute vegetable organisms known as microbes, and bacillus, and bacterium, which are found to play such an important part in the economy of Nature, and the knowledge of the operations of which have solved for us so many of its problems.

Viewed broadly, these infinitesimal bodies are of two kinds—those which grow in the presence of oxygen, and those which grow in the absence of oxygen. The former die if oxygen be withheld, the latter die if oxygen be applied. Speaking generally, the influence of the former is beneficent, the influence of the latter is maleficent.

It is not my intention to glance at, much less to review, the information we at present possess about microbic life, but I will refer to a subject which concerns us all no less seriously than that of which I have just been speaking—the presence of maleficent microbes in water. The great aim of the community is to have water supplied for drinking of

unimpeachable purity. I wish the community would insist upon their aim being carried out, and to this end the water is caught as it issues from the rock, and deep wells are sunk in the rock, from which the water is led to every house. So pure is this water in most instances that it contains only ten micro-organisms to the cubic centimetre. River water, on the other hand, teems with microbic life, there being often hundreds of thousands of beneficent micro-organisms to the cubic centimetre.

Doubtless maleficent microbes are constantly passing into river water, rendering it dangerous to drink. But if by chance maleficent micro-organisms should find access to pure supplies of drinking water the consequences are far more serious than is generally supposed, and the risk of drinking it is even greater than the risk of drinking from an ordinary river in bright sunny weather, when the life of beneficent organisms is most active.

If, for example, the microbe of enteric fever pass into pure deep well water it will live for five weeks, but if it pass into river water it will live only five days. The reason is this: the substances produced by the growth of beneficent organisms, which are so abundant in river water, destroy the maleficent organisms, whereas in pure deep well water the beneficent organisms are so few they do not produce sufficient microbic poison to interfere with the growth of the maleficent microbes.

Perhaps no more forcible illustration of the practical application of the knowledge obtained in the discovery of the existence of these minute organisms could be found than in the modern treatment of wounds. Before this time wounds healed slowly, and the healing process was associated with the formation of pus, or "matter," as it is popularly called. Poisons passed into the blood from these wounds, not infrequently giving rise to what is known as septic fever, and which often caused the death of the patient. It was discovered that the process of formation of matter—"suppuration" as it is called—was associated with the presence of large numbers of minute organisms which, it was found, were destroyed by certain substances, such as carbolic acid. If these were excluded pus was not formed, and the healing process was not interfered with. And now operations are done with comparative impunity which would not have been attempted twenty-five years ago, and other operations which then resulted in a mortality of 75 per cent. are now done with a mortality of 3 or 4 per cent. only.

Although the existence of these minute forms of life in the atmosphere and the soil was known, and that some soils teemed with them, and while their relation to animal life was being rapidly marked out, their influence upon the life of plants was apparently little thought of or even suspected until recently, and certainly no practical application of any discovery which investigation had made was arrived at. As yet comparatively little is known; but already the application of the knowledge gained is so valuable that we may hope for such further development as may advance materially both horticulture and agriculture.

The chemical analysis of plants shows they are made up of certain elements—oxygen, hydrogen, nitrogen, and carbon, together with lime, potash, phosphorus, and other mineral substances in the form of salts, and that these elements are in proportions which vary with the kind of plant. Now where do these substances come from? They must come obviously from the atmosphere or the soil in which the plants grow. The atmosphere contains oxygen and nitrogen as its principal constituents, in the proportion of four-fifths nitrogen and one-fifth oxygen, together with hydrogen in the form of water (which is a compound of oxygen and hydrogen), carbon in the form of carbonic acid (which is a compound of oxygen and carbon), and ammonia (which is a compound of nitrogen and hydrogen). Plants breathe through their leaves, throwing off water and carbonic acid gas; but during bright sunshine the leaves absorb carbonic acid gas, and their green colouring matter has the power of splitting this compound into its elements, retaining the carbon and giving off the oxygen.

The other constituents of the plant must be derived from the soil. If we grow crops of the same plant season after season in the same soil they presently become very poor, but by growing crops of different plants in rotation we are able to secure good crops. In order to maintain vigorous growth, and particularly in certain soils, and especially if we have to repeat frequently the same kind of plant, we manure heavily—that is to say, we enrich the soil with the elements which constitute the plant. Among these elements is nitrogen, and we apply it often in the form of nitrate of soda and sulphide of ammonium. But it has been found that upon analysing plants and the soil in which they are grown, they contain more nitrogen than could have been derived from the soil, and particularly in certain soils, and this is especially the case with papilionaceous or leguminous plants which produce a pod or legume as their fruit. This excess of nitrogen can only have come from the atmosphere, as there is no other possible source of it.

When plants are in active growth the microbes in the soil about their roots, and within them, are also in active growth. Without their aid plants could not live, for they prepare the food on which they live. In a drachm—a little old fashioned teaspoonful—of soil there are from 1000 to 75,000,000 of micro-organisms, which are found in greatest abundance within 3 inches of the surface, and are not present below 2 feet of it. It is by their aid the green colouring matter splits up the carbonic acid, and renders the carbon fit to be appropriated for the nutrition of the plant. It is they which abstract the nitrogen of the atmosphere, and render it fit for plant food, thus accounting for the excess of nitrogen. How this is done is not yet known, but it may be that hydrogen, which is particularly active in forming combination in its free state, is set free, and combining with nitrogen, forms ammonia, which is acted upon by the microbe.

The tubercles on the roots of leguminous plants are formed by their agency. They seem to require the carbon of the plant for growth, and return it nitrogen for its growth. When there is abundant nitrogen in the soil these tubercles are not formed, but when it is absent they become the habitat of the microbes which produce it. After a leguminous crop the soil is fit to grow a cereal crop, which it may not have been previously, a fact of which it would appear the ancients were cognisant. By the agency of nitrogen-forming microbes—and there would appear to be a different form of nitrogen-producing microbe for each genus of the Leguminosæ—nitrogen is stored up in the soil during the growth of the leguminous crop.

It may be that each genus of plants of other natural orders have their own particular attendant microbes preparing out of raw material the aliment they require; and in time many of these may be separated and cultivated, and applied to their particular functions with as great certainty as the acidifying and flavour-producing microbes are applied in the making of butter. When that time comes the economic value of the discovery must be enormous. Already some of the nitrogen-forming microbes have been isolated and cultivated in large quantities, and are now produced in a marketable form. On the Continent land which was infertile has yielded large crops after it had been sown with this nitrogen-producing microbe, and garden soils in which certain vegetables and flowering plants refused to grow are now luxuriant with them.

Judging by this success it would seem not unreasonable to anticipate the time when the life history of the microbes which influence the growth of plants will be as well known as those which affect milk, and that the practical application of the knowledge gained will be no less successful.—(Abstract of paper read by DR. GROVES at a meeting of the Isle of Wight Horticultural Association)

OUR BOTANICAL GEOGRAPHY.

IN studying the botanical geography of the British Isles, the leading important fact we find established is that they do not grow a single plant that is peculiar to them which cannot be found also in continental Europe. Another is that the plants found here do not all come from the same regions. In enumerating the various vegetable emigrations which, according to leading observers, have successfully colonised our islands, we may cite first the Asturian type, which, owing to the mildness of its winters, has long been established in Ireland. These Asturian specimens are the last representatives of a colony from the North of Spain.

The South-West of England and the South-East of Ireland exhibit a vegetation similar to that of Brittany and Normandy, which is termed the Armorican. Many of these are found along the western coasts of France till the increasing rigour of the climate north arrests their further progress. These plants, which are to be found with us mainly in the Devon and Cornwall districts on the coasts, have crossed to Ireland and have become naturalised in Cork and Waterford. The mountains of Wales, Cumberland, and Scotland present a peculiar vegetation entirely different from that of our plains. Analogous to that of Switzerland, it resembles even more that of Iceland and Greenland. It is termed the Boreal type.

What is termed the Germanic is the fundamental type of that of England. Originating in the north of Germany and France, it has in the course of ages become so predominant as to be called, but really this is a misnomer, the British type. Many plants found in England have never crossed St. George's Channel into Ireland. The marine plants of our isles follow the same laws of distribution as those governing the flora. A sea admittedly once covered most of the south of Europe and the north of Africa, for this is proved by the numerous identical shells found at numberless points from Greece to France. It follows that the upheaval of this ocean bed, which constitutes the last tertiary deposits, gave rise to a vast continent, comprising Spain, Ireland, the Azores, and part of Africa. This is from where the Armorican type found its way. The submersion of this continent was followed by a long period during which a lower temperature prevailed, and then it was that the migration of Arctic plants took place.

The oldest of these floras now comprising our vegetation would seem to be undoubtedly that of the mountains of the West of Ireland. The distribution of the second flora, next in point of probable date, depended on the extension of a barrier, the traces of which are still in evidence from the West of France to the South-East of England, and thence to Ireland. The third flora depended on the connection of the coasts of France and England towards the eastern part of the Channel.

Of the former existence of this union no one can entertain a doubt. The distribution of the fourth or Alpine flora of Scotland and Wales, was, it would appear, effected during the glacial period, when our mountain summits were low islands extending to Norway through a glacial sea, and clothed with an arctic vegetation, which in the gradual upheaval of those islands, and consequent change of climate, became limited to the summits of the newly formed and still existing mountains. The distribution of the fifth, or Germanic flora, depended upon the upheaval of the bed of the glacial sea, and the consequent connection of England with Ireland, and also with Germany, by great plains, the fragments of which are still existent, and upon which many now extinct great animals lived. The breaking up, or rather submergence, of the first barrier led to the destruction of the second, and then that of the second caused that of the third; but the well-marked epoch of migration of the German flora clearly indicates the subsequent formation of the Straits of Dover of the Irish Sea as now existing.—WM. NORMAN BROWN.

OUR NEXT ISSUE.—As intimated last week, the next issue of the *Journal of Horticulture*, June 24th, will be devoted, not to descriptions of the Queen's Gardens only, but to methods of procedure in them—a blend, it is hoped, of matter of interest and usefulness, for almost every feature in gardening, ornamental and serviceable, will be represented. This will be supplemented by Mr. D'Ombrain's review of *Horticulture*, and the changes brought about as he remembers them during the past sixty years. Though the number will be considerably enlarged, its whole space will be occupied in "Honour of the Queen," and neither communications in hand, or which may be received during the ensuing week, nor reports of shows, can possibly appear till the issue succeeding. We have reason to believe that the change from ordinary routine during something like a holiday week, consequent on the passing of a great historical event, will be equally acceptable to amateurs and gardeners.

—EVENTS OF THE WEEK.—Rose shows have now started in real earnest, and the list of fixtures of which we have been informed will be found on page 524. On Wednesday, the 23rd inst., the Victorian Era Flower Show will be held at the Crystal Palace, while the Old Deer Park, Richmond, will be *en fête* with the Richmond Horticultural Society's Exhibition.

—WEATHER IN LONDON.—The weather in the metropolis during several days of the past week and the early days of this was of a quite tropical character. Thursday and Friday were fine, and Saturday was magnificent, the sun shining with great power. The thermometer reached 77° in the shade, this being exceeded on Sunday by 7°, 84° in the shade being the maximum. Monday was duller and a trifle cooler, Tuesday again being bright and warm, but more pleasant, owing to breezes that prevailed throughout the day. Yesterday (Wednesday) was cooler, and rain fell at intervals.

—WEATHER IN THE NORTH.—The weather for the past fortnight has been extremely variable. Saturday, the 5th inst., was the warmest day of the season, the thermometer showing 79° in the shade. On the morning of the 8th Potatoes and tender foliage were in some districts blackened by a sharp frost. Thunder and very heavy rains have latterly been prevalent, and on Tuesday morning the air was distinctly cold.—B. D., S. Perthshire.

—MANCHESTER SHOW.—Our reporter writes:—"By an oversight I omitted to mention that the medals, awarded to Messrs. Sander & Co., H. Low & Co. (both having splendid exhibits), and Charlesworths at the late Show were all large and of equal value. May I also bear testimony to the choice stand of hybrid *Cypripediums* staged by Mr. Chapman, gardener to R. I. Measures, Esq., Camberwell, for several of which Mr. Chapman had the honour of receiving certificates. I should also like to say how much the success of the Exhibition was due to their courteous attention to all and interest taken in every possible way by Mr. Weathers, the new Curator, and his assistant Mr. Paul."

—EXHIBITION AT GHENT.—The programme of the fourteenth International Horticultural Exhibition of the Société Royal d'Agriculture et de Botanique de Gand has reached us. From this it appears the show will be the 163rd that has been held under the auspices of this Society, and the dates fixed are from the 16th to the 24th of April, 1898. The schedule forms a book of nearly 100 pages, and comprises twenty-eight sections, amongst which are divided 716 classes. The President is Count O. de Kerchove de Denterghem, and the Secretary Mons. E. Fierens, of whom we gave a photograph a short time back. We hope to make further reference to this show at a future date.

—THE CRYSTAL PALACE VICTORIAN ERA FLOWER SHOW.—Judging by the schedule, this show, to be opened on June 23rd, should be both interesting and imposing. It is to be essentially an exhibition of groups—of Begonias, Caladiums, Cannas, Coleuses, Ferns, Coniferae, fine-foliaged plants, Gloxinias, Alpines, hardy herbaceous plants, Orchids, Palms, Pelargoniums, and Roses, the prizes ranging from £20 downwards. In addition, Crystal Palace commemorative medals are provided for the best group of miscellaneous plants arranged for effect in a space of 300 square feet; also for the best group of plants introduced during her Majesty's reign, arranged in a space not exceeding 500 square feet. Money prizes are also provided in these classes. There are only twenty-six classes in the schedule, but they are of a nature to afford scope for a grand exhibition, worthy of the occasion and of the Palace. There must be no delay in sending entries to Mr. G. Caselton, garden superintendent, and a request in the schedule should not be ignored—namely, that those who have entered, and find that they cannot exhibit, send a telegram, or communicate to that effect, to Mr. Caselton, the day before the show. This will be most helpful to the manager, and add materially to the effect of the exhibition.

— **SEATS TO VIEW THE JUBILEE PROCESSION.**—A reference to our advertisement pages will convey to readers an idea of the excellent seats that are to let to view the Jubilee Procession on Tuesday next. Applications should be made to 171, Fleet Street, E.C.

— **DEATH OF MR. C. R. HUMBERT.**—The death occurred on Thursday, June 3rd, at his residence in Watford, of Mr. Charles R. Humbert, head of the firm of Messrs. Humbert, Son & Flint, auctioneers, surveyors, and valuers, of Watford and Serle Street, London, W.C. Mr. Humbert was in his forty-third year. He was honorary secretary of several local organisations having for their object the promotion of the interest of agriculture and horticulture.

— **HOW TO GROW BEGONIAS.**—Such is the title of a book that has just been published at 2s. by Messrs. Sampson, Low, Marston & Co., from the pen of Mr. G. A. Farini, F.R.H.S., the well-known grower and exhibitor of these mostly popular flowers. The book, which is well printed on good paper, contains upwards of 130 pages, amongst which are distributed a few illustrations elucidatory of the text. Eighty pages are devoted to the cultivation of the plant, and the style in which it is written will allow the greatest tyro to grasp the meaning. The remainder of the book comprises a catalogue of some of the best varieties at present in cultivation.

— **BEDFORD SHOW.**—In the Corn Exchange, Bedford, on Thursday, July 8th, the Bedfordshire Horticultural Improvement Association will hold its Show. The schedule comprises six classes only—namely, for a group of miscellaneous plants; for twenty-four Roses, not more than two of one variety; for twelve Tea Roses, distinct, three blooms of each; for twenty-four bunches of hardy herbaceous or bulbous plants, distinct; for the most tastefully arranged table decoration, each of these being open to all; and another for members of the Society for twelve cut Roses, not more than two blooms of any one variety. We hope the entries will be numerous and the quality high, in order to make up for the somewhat striking scarcity of classes. The Hon. Secretary is Mr. E. Laxton, 63A, High Street, Bedford.

— **NON-PRODUCTIVE STRAWBERRY PLANTS.**—In April of 1896 I planted out a bed of President Strawberry plants (runners). These grew amazingly in the fresh piece of ground prepared for them, and the plants are now enormous for their age, but, alas! not one in ten has a flower on it. On one side of them I planted seven rows of Royal Sovereign, and there is scarcely a plant which is not carrying a good crop of fruit. On the other side of the Presidents I planted a number of Vicomtesse H. de Thury from side crowns of old bearing plants; every one of these is carrying a full crop. Next these were planted a bed of British Queen, also from side crowns of fruiting plants; these also are covered with flowers and immature fruit. When I first began growing British Queen Strawberries I planted runners in the autumn, and was troubled by having a number of unfruitful plants; now I never grow them from runners, but always from side crowns taken from fruitful plants in April just when they are emitting fresh roots. This plan is far better than planting runners, unless you have early prepared runners, and it has the merit of having all fruitful plants instead of a proportion of non-fruiting ones.—F. BOYES, *Beverley*.

— **JUBILEE OF A GREAT FIRM.**—"Gishurst" and "Gishurstine" are terms well known in the gardening world, and both of them as gardeners' friends, the first as forming a long-proved and excellent wash for plants and trees in destroying insects, the second as a waterproofing and preservative of boots. It may not be so well known that these are small items in the great business of Price's Patent Candle Company, the head-quarters of which are at Battersea. We have received a beautifully printed and illustrated Jubilee memorial of the firm, and find that it was formed by Mr. William Wilson in 1847, who was the first Chairman; while his sons, Mr. James P. Wilson and Mr. George F. Wilson, F.R.S., the ardent horticulturist, Managing Directors, the last named alone surviving, and a valuable Director still. It was he, no doubt, who invented the two articles named, and we also find that the world is indebted to him not only for the production and subsequent cheapening of the superior wax composite candles, now universally used, but for that most valuable medical and commercial necessity—pure glycerine. It seems that a stimulus was given to the improvement in candles by the marriage of the Queen, when the demand was so great for placing them in windows for general illumination—a candle to every pane, having a remarkable effect. That custom has been long superseded; but it may not be generally known that "night-lights" are extensively used for the small pendant-coloured glasses, used in present illuminations. Of these lights enormous numbers have recently been supplied by "Price's," one order alone being for 1½ million in view of her Majesty's Diamond Jubilee. Two thousand persons are employed by Mr. Wilson's firm, and nearly 1800 were recently taken to the Crystal Palace in special trains, and entertained at a bountiful repast, each adult worker being further presented with a new crown piece and the juniors with half a crown. A pension fund is also maintained by the firm, as provision for workers in their old age. The firm is increasing in wealth and prosperity under the management of Mr. J. Calderwood, and as will be seen the workers who have helped to make it so have not been forgotten, the kind consideration shown in many ways to the employes having being instituted by Messrs. William, James, and George F. Wilson.

— **CROYDON SHOW.**—The Croydon Society has been successful in obtaining by special subscriptions a very handsome new cup to replace the last, which was won outright in 1896 by the Rev. J. Pemberton, after being in competition for nine years.

— **WOLVERHAMPTON HORTICULTURAL CLUB.**—The monthly meeting was held at the Star and Garter Hotel, on June 1st, when Mr. Baillie, of Messrs. Dickson's, Chester, gave a most able and instructive lecture upon "Herbaceous Plants and their Cultivation," a subject with which the lecturer was well able to deal. Unfortunately the lecturer was not able to remain to hear the discussion which followed.

— **MR. R. INGLIS.**—We learn that our old correspondent, Mr. R. Inglis, has relinquished the charge of General Leigh Pemberton's gardens at Abbots Leigh, Hayward's Heath. Mr. Inglis is a gardener of great experience and high respectability. Equally competent both as a cultivator and in landscape work, he would take special interest in laying out a new garden or renovating an old one. His address is Aberdeen Cottage, New England Road, Hayward's Heath, Sussex.

— **REIGATE SHOW.**—The eleventh annual exhibition of the Borough of Reigate Cottage Garden and Horticultural Society will be held in the grounds of the Priory, Reigate, on Wednesday, July 7th. The schedule is a bulky one divided into several sections, and comprising 180 classes in all. Roses have been a feature in past years, and it is to be hoped that they, as well as fruits, vegetables, plants, and flowers, will again be well shown. The Honorary Secretary is Mr. M. Puntton, St. Mark's School, Reigate, to whom all communications must be addressed.

— **SHEFFIELD CHRYSANTHEMUM SOCIETY.**—The June meeting was held on Wednesday, the 9th inst., in the Society's room in the Museum, Orchard Street. The essay was "Plants for Grouping, and Grouping for Effect." The essayist was Mr. M. H. Willford, a successful exhibitor of groups of plants at our Sheffield exhibitions, who enumerated a long list of plants which he considered most suitable for the purpose, and gave excellent instructions for arranging plants to give the best effect when grouped together. The essay was a very instructing one, and ably treated the subject. After a short discussion a vote of thanks to Mr. Willford was passed. The monthly exhibits were Gloxinias for professional members. Some very good plants were staged. Mr. C. Scott was awarded first prize, Mr. G. Smith second, and Mr. C. Shorten third. The amateur exhibits, pot plants in bloom, were disappointing, as only one exhibit was staged, by Mr. R. Gascoign, who had thus no difficulty in scoring. Mr. John Haigh presided over the meeting.

— **MARKET GARDENERS' COMPENSATION IN SCOTLAND.**—At a recent meeting of the Standing Committee on Trade, the Market Gardeners' Compensation (Scotland) Bill was under consideration. The object of the Bill is to extend to holdings which are used as market gardens the provisions of the Agricultural Holdings (Scotland) Act, 1883, as to tenants' improvements. The chief amendment, in the form of a new clause, moved by the Lord Advocate, was to the following effect:—"Any compensation payable under this Act shall, as regards land belonging to her Majesty the Queen, her heirs and successors, in right of the Crown, be paid in the same manner and out of the same funds as if it were payable in respect of an improvement mentioned in the first part of the first schedule to the principal Act, except that compensation for planting Strawberry plants and Rhubarb and other vegetable crops shall be paid in the same manner and out of the same funds as if it were payable in respect of an improvement mentioned in the third part of the said schedule." With this amendment, says a contemporary, the Bill was ordered to be reported to the House of Commons.

— **THE RAINS.**—Immense benefit has resulted to all descriptions of crops from the recent rains, although in some districts heavy hail and tremendous downpours on Whit Sunday did considerable harm. The way in which Strawberry plants have recovered from the cold winds and sharp frosts of last month is remarkable, and now there is every prospect of being an unusually heavy crop. We may expect to see the fruits cheap enough in the Jubilee week. All trees and bushes have had a good cleansing, and now making strong growths and good leafage are getting quite out of harm's way. As generally the fruit crop is very light, it is not desirable that wood growth should be too luxuriant, but we must accept what is provided. Amongst all vegetables the effects of the rains are wonderfully apparent. Peas have not only made very strong growth, but are blooming luxuriantly. We ought to see a splendid crop of fine, well-filled pods. So far even the common field earlies are better filled than I have seen them for some years. As to the Marrow section, they will soon be in, and then Peas will be good and very cheap. Potatoes, no doubt, in many cases through tops having been cut with frost, came very irregularly, but they have greatly recovered, and are now putting on strong growth. As much may be said of Beans, the Broads, especially, being very clean and good. There seems little doubt now but that, in spite of the ungenerous nature of the weather last month, we shall have a fine produce year, fruit unfortunately excepted. Hay should be wonderfully abundant, and in many directions mowing of heavy swathes has already begun. The Jubilee year should be a plentiful one.—A. D.

— MAY WEATHER AT HODSOCK PRIORY, WORKSOP.—Mean temperature, 50.2°. Maximum in the screen, 70.5°; minimum in the screen, 30.3°. Minimum on the grass, 20.1°. Frosts in the shade three, on grass fifteen. Sunshine, 233 hours, or 48 per cent. of the possible duration. Rainfall, 0.88 inch. Rain fell on ten days. A bright and dry month, with cold nights and northerly winds. Vegetation is backward.—J. MALLENDER.

— THE WEATHER LAST MONTH.—May was very changeable, with temperature and rainfall below the average and more sunshine than usual. The wind was in a northerly direction eighteen days. Total rainfall 1.09 inch, which is 1.27 inch below the average for the month. This fell on eleven days, the greatest daily fall being 0.23 inch on the 31st. Barometer (corrected and reduced), highest reading 30.469 inches on the 16th at 9 A.M.; lowest reading, 29.349 on the 28th at 9 P.M. Temperature: highest in the shade 68° on the 31st; lowest, 31° on the 11th and 12th. Mean of daily maxima, 59.03°; mean of daily minima, 40.80°. Mean temperature of the month, 49.91°; lowest on the grass, 25° on the 13th; highest in the sun, 131° on the 17th. Mean of the earth at 3 feet 49.06°. Total sunshine, 209 hours 35 minutes. There were no sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— CLAY'S SUCCESSFUL GARDENING.—Though our pages are full, as a neat little handbook bearing the above title arrives we must make room for a few lines respecting it, as we shall have no space available next week. It may be concisely described as a good book, written by good men, in advocacy, presumably from their experience, of a good manure. That is the case in a nutshell. It is, perhaps, scarcely necessary to say more, though possibly some readers may like to know who the "good men" are. They are Messrs. George Gordon, T. W. Sanders, J. Udale, H. Shoesmith, H. C. Prinsep, A. J. Rowberry, G. Triuder, J. Hudson, W. Iggulden, and J. Fraser, all of whom are competent, and treat well the different subjects of plants, fruits, or vegetables with which they have been entrusted. Then by way of adornment, the book contains an article on Floral Decoration, by Miss Edith Chivers, gold medallist R.B.S., plus three charming photographic illustrations. This shilling handbook of 124 pages is published by Messrs. Clay & Son, Stratford, and E. W. Allen, 4, Ave Maria Lane, E.C., and will doubtless find its way into the hands of many amateurs and gardeners who may benefit by the information imparted in its pages.

— EARLY PEAS.—The first market or field Peas were gathered in West Middlesex (always a fairly early district) on June 10th, and were Eclipse. The sample was, for first picking, unusually good. This variety, which has larger and greener pods, has materially displaced Sangster's No. 1 from field culture in that market growing locality. Formerly the old Harrison's Glory, a fairly early and hardy round blue Pea, followed; but I notice this year some good breadths of that excellent dwarf variety, William Hurst. This, sown in rows at 18 inches apart, gives an enormous crop of nice pods from a large breadth. Harrison's Glory is a hard, dry eating Pea, but W. Hurst has distinct marrowy texture and flavour. It is surprising how few out of the myriads of Peas put into commerce suit the requirements of the market grower. Gradus is, without doubt, one of the earliest Peas in cultivation, the pods being large, long, and green; but as grown under ordinary field culture it lacks robustness, is thin of growth, very long jointed, and far from a free cropper. Ameer, also early, is rather better, but later, yet of the same long-jointed habit. Such varieties as Senator, Daisy, Early Defiance, and Oracle, all very robust, dwarf, and free croppers, rank amongst the best second earlies for laying in fields. Of twenty varieties being so tested this season, I hope later to indicate not only their stages of earliness, but their cropping qualities.—A. D.

— THE SOURCE OF ABIETENE.—Abietene is the volatile product from the resin of some West American Pines, and is the counterpart of turpentine, which is distilled from the resin of some other Pines, chiefly those in the Southern United States. Abietene is a more volatile liquid than turpentine, but both are hydrocarbons, although belonging to different series. About the year 1878 samples of abietene were received in Philadelphia, with the statement in one case that it was the product of *Pinus Sabiniana*, and in another case that it was derived from *P. ponderosa*. Of recent years it has come to be understood that the commercial source of abietene is *P. Jeffreyi*. As I had in my possession the barks from *P. ponderosa* and *P. Sabiniana*, it occurred to me that something might be learned by examining the volatile product of these two samples. They were accordingly distilled, and, while the yield was small, it was enough to get the characteristic orange odour of abietene in both cases. In another experiment the amount of volatile oil in the bark of *P. ponderosa* was determined to be about 0.2 per cent. The bark, therefore, would not be a profitable source of the oil. It is probable that both *P. ponderosa* and *P. Sabiniana* have yielded samples of this oil, although it may be possible that *P. Jeffreyi* is at present the commercial source. Some years ago Professor Wentzell of San Francisco detected oil of turpentine in the resin of *P. ponderosa*. It is possible that both oils occur in different parts of the tree. Unfortunately the commercial production of abietene and its resin is in the hands of a medicine company, which is disposed to attribute to these products curative virtues they do not possess.—HENRY TRIMBLE (in "Garden and Forest.")

— PRESENTATION TO MR. CUMMING.—Mr. Cumming, for some years gardener to Lady Gough, at St. Helens, Bootstown, was the recipient of an interesting address and presentation on the occasion of his departure from Ireland. The presentation was taken part in by a very large number of friends and well-wishers, and took the form of a valuable gold watch for Mr. Cumming, and a beautiful gold brooch (shamrock pattern) for his wife. The presentation took place at a dinner given in the Grand Restaurant, Lower Sackville Street, Dublin, and was very largely attended.

— CAMBRIDGESHIRE HORTICULTURAL SOCIETY.—The schedule of the three shows to be held under the auspices of the above Society has been sent to us by the Hon. Secretary, Mr. A. Matthew, 20, Trinity Street, Cambridge. The first one, at which the President, A. Peckover, Esq., is offering a special prize for thirty-six Roses, is being held to-day (Thursday). The second show is fixed for September 9th, and comprises classes for cut flowers, fruits, and vegetables. Exhibition No. 3 will be held on Thursday, November 11th, when Chrysanthemums will be the principal attraction. Most of the classes in each show are apparently restricted to members of the Society, but in November there are two open to all for thirty-six Japanese, distinct, and twenty-four incurved, in not less than eighteen varieties. The last two shows will be held in the Corn Exchange, and schedules may be had from the Secretary at the address given above.

— EARTHWORMS.—A discussion on the subject of earthworms and vegetable mould appeared in a recent issue of "Longman's Magazine." The writer, Grant Allen, states that it was Gilbert White of Selborne who first of all pointed out the importance of earthworms as producers and maintainers of the living layer of vegetable mould. It was the patient investigations of Darwin, however, which fully established the fact, and raised it to the rank of a scientific discovery, his first writing on the subject appearing in the "Gardeners' Chronicle." Later he issued an entire book on this interesting matter. Darwin showed that earthworms act upon the soil in three ways. In the first place they open up and loosen the ground for the roots to penetrate, more perfect aëration of the soil being thus obtained. The acids they secrete also act chemically upon the layer of rocks beneath in a way that assists the disintegration of the latter. In the second place they crush in their gizzards small fragments of stone and liberate their component elements. In the third place they drag down into their burrows countless numbers of leaves, which they eat, and carry up the refuse to the surface. It is computed that no fewer than 53,000 worms inhabit an acre of garden soil. These worms pass through their bodies 10 tons of material in a year, and throw it up as mould at the rate of 1 inch in depth every five years. The greater part of this mould is composed of a refuse of vegetable matter, and is teeming with myriads of bacteria. Even after allowing for other co-operating causes, earthworms are responsible for the formation and renewal of this layer of vegetable mould.

— THE CASTOR OIL PLANT.—The Castor Oil plant has been cultivated since the earliest historic time, and specimens of it supposed to be over 4000 years old have been found in Egyptian tombs. It is perennial in India, its native country, but as it has spread into less congenial climates it has lost that habit, like the Cotton plant, and is known to us as an annual. It is commonly supposed that the plant will grow wherever Indian Corn will thrive, and this is true where it is meant to be used as an ornament; but a recent circular published by the United States Department of Agriculture points out that it can only be grown effectively in commercial quantities in warm climates, since its only value is the oil content of the seed, and the general truth which is applicable to nearly all oil-bearing plants holds in regards to this one—namely, the warmer the climate the larger the per cent. of oil. Some varieties of the Castor Oil bean will mature seed in the northern half of the Indian Corn belt of the United States, but the plant cannot be cultivated there so as to yield paying quantities of oil. It needs a deep, fertile, loamy, friable, and well-drained soil, and then where the climate is sufficiently warm it will yield from 20 to 25 bushels of beans to the acre, containing from 50 to 60 per cent. of oil. The seeds, after being soaked for twelve hours in tepid water, should be set 5 or 6 feet apart each way, two in a hill, and when 3 or 4 inches high the weaker plant should be removed. The weeds should be destroyed, and the ground kept loose by surface stirring. The seed spikes should be collected as soon as the pods turn brown, and before the seeds drop out of the pods in handling, and placed in the sun until the seeds are partly free from the pods. Frequent gatherings are necessary, so that only such spikes are removed as are in proper condition. The seeds are first cleaned; then, after being gently warmed, are placed under a screw press, which liberates a whitish liquid. This is mixed with water and boiled for some time, and the impurities are skimmed off as they rise. Clear oil is at length left on the top of the water, the mucilage and starch being dissolved and the albumen coagulated by heat, forming a whitish layer between the oil and the water. The oil is further clarified by boiling, which drives off the acrid volatile matter. The Italians have a special method of preparing the oil which rids it of its nauseous flavour, and in this country medicinal oil is manufactured by cold expression from the crushed beans—"Garden and Forest.")

EPIDENDRUMS.

THE genus *Epidendrum* is the largest, numerically, in the order, and consists of an immense variety of plants so different in habit and inflorescence that one can hardly imagine they are members of the same genus. The name of the genus was doubtless suggested by their habit of growing, and as a matter of fact Linnæus included every exotic Orchid in it. But the great botanist could never have foreseen what an immense number of species the order would be found to contain when, as has happened, their lovely colours, graceful forms, and other beautiful features have led to their being searched for by enthusiastic collectors in every part of the world.

Thus the genus grew until it was quite impossible to suitably classify them all, and later botanists, as Swartz, Lindley, and Reichenbach, have broken them up into other genera. The residue is a very mixed lot of plants, some of undoubted beauty and first-rate garden plants, others miffy under cultivation, though handsome, while a large number are of no value whatever to the horticulturist, though interesting to botanists. The latter are, in fact, the weeds of the Orchid family, and unless a rare or unknown kind, are best relegated to the rubbish heap. It is a widely distributed genus, geographically extending almost from end to end of the American continent, and occurring in nearly all the adjacent islands.

Owing to this wide distribution, it is not possible to give a method of culture that will suit all the species; but, as a general rule, it may be conceded that all species having the *Cattleya* habit, such as *E. fragrans*, *E. cochleatum*, and *E. ciliare*, may be grown in an intermediate temperature, such as suits Brazilian plants generally. The dwarfier kinds, as *E. vitellinum*, do with less heat, thriving with the *Odontoglossums* or *Masdevallias*, or better still with the Mexican section of *Lælia*. One well-known exception may be noted in the lovely *E. bicornutum*, a species hailing from the West Indies, and requiring great heat to do it well.

It must be confessed that this plant is difficult to grow for many years under our artificial treatment, but it is worth obtaining if only for the sake of a couple of years' inflorescence. The best of all places to grow it is an almost unshaded part of the East Indian house, the plants being grown in pots close to the light or suspended from the roof in baskets. Peat fibre is not to be recommended for this plant, or at all events only a little. *Sphagnum* moss is a much better material, and a thin layer only of this must be placed over abundant drainage. Keep the plant on the dry side while at rest and until new shoots have started, but after this they may be treated very liberally as regards moisture, both at the roots and atmospherically. Close the house early during the growing season, with plenty of moisture and the sun shining fully upon the plants, and you have just the kind of atmosphere that *E. bicornutum* delights in.

It is a very singular fact about this Orchid that the base of the bulb splits vertically for a short distance, and being quite hollow forms a home for swarms of ants. These insects should if possible be kept away from the plants, as they can do no good, and are very unsightly. Thrips, too, are fond of the succulent young growths, and must be kept at bay if possible by sponging. The flowers of *E. bicornutum* are produced on erect scapes from the apex of the pseudo-bulbs, and are pure white in ground colour, the lip, and in some varieties the sepals and petals, dotted with purple, and provided with two horn-like processes, from which it takes its specific name.

E. ciliare is a very pretty plant, worthy of a far greater share of attention than it receives at the hands of cultivators. The flowers occur on erect scapes of about five or six, and are greenish white on the narrow sepals and petals, the beautifully fringed lip being pure white. It is an old species, having been introduced to British gardens as far back as 1790; it is widely distributed in South and Central America, and often arrives amongst importations of *Cattleyas*. *E. cochleatum* and *E. fragrans* are similar habited kinds, the flowers of both occurring on upright spikes, and having in each case the lips uppermost, this organ being almost shell-like in appearance. Both are old species, having been in cultivation over a century, and they are natives of various of the West Indian islands.

The section with tall reed-like stems, such as *E. evectum*, *E. radicans*, *E. Parkinsonianum*, *E. xanthinum*, and many others,

are an interesting free-blooming class of plant, which cannot here be discussed in detail. The blossoms usually occur in globose heads from the end of the stems, the last named, for instance, producing large golden yellow balls of flower, that lighten up many a house during the early spring months. They all like a fairly liberal mode of culture—a good root run, plenty of moisture, and a position not too much shaded. *E. vitellinum* is one of the most useful of all cool Orchids, free and constant in blooming, and of bright effective colour. It is very easy to grow in a cool moist house, and is a native of various parts of Mexico. It first flowered in England in 1839.—H. R. R.

COOMBE WOOD.

THE neighbourhood of Kingston Hill has long been celebrated for its many horticultural features, and amongst them the Coombe Wood Nurseries have not been the least famous. For years travellers on the road to Kingston can remember the splendid shrubs that are growing there, and many will have noted the handsome avenue of *Wellingtonia gigantea*, alternated with *Araucaria imbricata*, that runs down the centre of the ground into the valley beyond. Now there is a change, for the *Wellingtonias* have been removed, and perhaps the *Araucarias* will some day have to follow in their footsteps. When they are gone passers-by will miss a landmark that had long been familiar, but there will still remain the thousands of coniferous and other trees that proclaim the Coombe Wood Nursery of Messrs. Jas. Veitch & Sons, Ltd., whose reputation as horticulturists is world-wide.

Visits almost numberless have been paid by the writer to the firm's head-quarters at Chelsea, with its great area of glass houses; to Southfields, Fulham, where trained fruit trees are at home; and to Langley, near Slough, where hardy fruit trees of all shapes and kinds, hardy herbaceous flowers and Roses combine to interest the visitor, but until Friday last Coombe Wood in all its beauty had not been seen. Many times it was almost reached; failure succeeded failure until now, when it was fully realised what had been missed. For this is one of the most charming and interesting nurseries in the United Kingdom. Occupying three sides of a valley, one may from vantage points on each side get views that would never be dreamed about when on the level of the hill-top. One picture presents flowers, shrubs, with Wimbledon Common in the background; another similar vegetation terminating in the deep crimson of some *Acers*; and a third, looking from the last-named plants, shows *Rhododendrons* of many sizes and shapes, which, though past their best, were still a blaze of colour.

Starting from the main entrance we (Mr. Jas. H. Veitch, Mr. Howard, and the writer) first made our way to the several houses containing many thousands of Roses in pots. These are arranged in long, low, span-roofed pits, and the number of plants is nothing short of surprising. Their condition as regards health and cleanliness leaves nothing to be desired, and the same may be said of the hundreds more that are stood outside. House after house contains nothing but these, while others are occupied with plants that are rarely seen in gardens—some, indeed, that have never been seen at all, for they have been imported by this enterprising firm, and are now under trial. And very severely are they tested ere they are allowed to be put into commerce. Then there are in a warmer house plants that are being forced into flower for the Jubilee, all of which give abundant promise of future beauty.

Though there are many rare plants within these structures, others find a home on their wall outside. These include *Ivies*, *Olearias*, *Escallonias*, *Hollies*, and scores of others. Mention may also be made of *Rosa Wichuriana* (*Luciæ*), which is such a favourite plant in America, where it is said to ramble over banks, and appear nothing but a mass of bloom in its flowering season. Considering its beauty, it is somewhat surprising that we do not see more of it in places in this country. Perhaps when it becomes better known it will be more appreciated. Many of the plants represented here and in other portions of the nursery would probably not be met with elsewhere except in botanical gardens, and not always in those. This cultivation of plants that are rarely asked for reflects much credit on the firm.

Passing from the houses we enter almost immediately upon a path flanked by two broad borders planted with all kinds of shrubs and trees as specimens. Little plants of *Olearia stellulata*, about 2 feet high, are smothered with their white Daisy-like flowers, and

produce a singularly beautiful effect amongst the various colours of the leaves of the several shrubs and trees. *Olearia Gunni*, with branches roped with flowers, is also charming. *Berberis* there are almost without number, some with large leaves, and others

Another shrub we noticed was *Cæsalpinia japonica*, which was originally introduced by Messrs. Veitch from Japan. Unfortunately the habit is not very good, but the handsome canary yellow flowers, with their red filaments and anthers, more than compensate

FIG. 100.—*CÆSALPINIA JAPONICA*.

with small ones. Of the former *B. aquifolium latifolium* has very handsome foliage, especially in the young state. *Hydrangeas*, *Viburnums*, *Syringas*, and *Weigelas* rise here and there to command attention. Of the last-named *Weigela rosea* Eva Rathke, with very deep rose coloured blooms, is almost perpetual flowering.

for this. The blooms are borne in long racemes, carrying upwards of twenty individual flowers. Of this we give an illustration (fig. 100). The plant is perfectly hardy. *Eucryphia pinnatifida*, which was figured in the *Journal of Horticulture* some time back, though not now in flower, is beautiful by reason of its foliage alone.

The Japanese Witch Hazels (*Hamamelis*) will be familiar to visitors to the Drill Hall, where they are often shown in the early spring months from Coombe Wood. A beautiful leguminous plant is *Hedysarum multijugum*, of which the purple flowers are produced with great freedom. The collection of *Nymphæas*, comprising Marliac's superb hybrids is very complete, and of the greatest interest.

One might continue mentioning flowering or foliage shrubs for still a very long time, but with one or two more we must draw to a close, as there are several other plants to which reference must be made. However, the *Stuartias* with their *Came'llia*-like foliage and clear white flowers, and *Styrax obassia* (see illustration fig. 97, page 507) must on no account be omitted. Another point in connection with these, apart from the beauty of the flowers and of the leafage, is their general good health. Here and there one may come to a plant that has suffered from transplantation, but the vast majority are in splendid condition, this applying to large and small alike.

The Coombe Wood collection of *Acers* is remarkable for nothing more than for its extent, for it comprised most, if not all, the best in cultivation at the present time. These Japanese Maples, with their beautiful leaves, are fast becoming popular, and deservedly so, for nothing looks more beautiful in the border than these. Planters were at one time rather shy of them, doubting their hardiness; but all fear on this score may now be removed, for on the somewhat cold soil at Coombe, and in exposed situations, they have stood uninjured for a number of years. They are well deserving of all the popularity that can possibly be accorded to them. Both the varieties of *A. japonicum* and *A. palmatum* and others are worthy of close attention for association with the other occupants of borders and shrubberies.

In a previous paragraph brief reference was made to the *Rhododendrons* as adding materially to the beauty of one of charming views. Now we must advert to them to call more specific attention to their variety, quality, and health. It is not proposed to give any names, but simply to refer to them as a whole. There are bushes and standards, every one of which has contributed, or is now doing so, to the interest of the collection. Some are light in colour, others are dark, but all are of the finest quality, while the deep-hued stout foliage creates the impression of sound health. These alone, when at the summit of their beauty, are well worth a journey to see. Hardy *Azaleas*, too, are of great beauty and in extensive variety.

The number of trees of almost all kinds that are grown is enormous, and the differences noticed in walking round are wonderful. There are Coniferous trees by the thousand, representing all those that can be cultivated at Coombe, and of all sizes, from the tiny plantlet to the shapely specimens. Other trees equally as good in health as the Conifers are numerous, and include Chestnuts, Limes, Planes, Sycamores, Walnuts, *Ailantus*, Hornbeams, with many besides. *Cerasus* are largely represented, as are *Pyruses*, while the *Magnolias* form a complete representative collection. They comprise *Watsoni* (of which the courtesy of Messrs. Veitch permits of our giving an illustration, fig. 101) *hypoleuca*, *Soulangeana nigra*, *parviflora*, *stellata*, *conspicua*, *macrophylla*, and several others. For these handsome plants the firm has a large demand, and frequently experience some difficulty in coping with it.

One of the finest features of the whole establishment is the collection of *Bamboos*, which is nothing less than a remarkable one. The visitor may see nearly every species or variety in cultivation, some with delicate-looking growths and others with very strong. The firm was prompt to recognise their utility for various situations on an estate, and with its usual enterprise commenced to make the stock as complete, succeeding in a highly creditable degree. Those who are interested in *Bamboos*, and desire to make close comparison, would find ample material to work upon at Coombe Wood, whence specimens have from time to time been shown at the Drill Hall.

Such notes as have found a place in the preceding paragraphs are incomplete in many respects, but to give an exhaustive reference to every variety and kind would be demanding too much space. They must therefore suffice for the time being, and readers will do well to make the notes of more practical utility by going to Coombe Wood to see for themselves. For his own part the writer is determined that, though it took years to make the first visit, it will be by no means years ere he makes another.—METROPOLITAN.

THE EFFECTS OF A STORM.

I NOTE in the Journal that on Sunday, June 6th, in London there was a thunderstorm with rain. Here we experienced one of the most terrific storms I ever remember. The early part of the day was very warm and sultry, and between three and four o'clock it became almost dark. The rain and hail then commenced to fall in torrents, so much so that within three-quarters of an hour, not more, we registered 1.53 inch of rain, consequently all low-lying places were flooded, as no drains could carry off the water as fast as it descended. Roads and paths were for a time like rivers, and tons of earth and sand were washed away. A short distance from where I am writing a fine Oak was struck by lightning, the trunk being stripped of bark, and split in twain. The tops of Potatoes, Beans, and Peas were cut off, while Lettuce cut into ribbons. Beet, Carrots, Onions were either cut off, washed out, or battered into the ground.

I thought we must have had the worst of the storm, but it was not so, for yesterday I visited Elmstead Lodge and Elmstead Grange (about a mile away), the scene there almost baffles description. Herewith I enclose a few samples of the damage done that you may form some idea of same. Mr. Blackburne, Elmstead Grange, is a noted grower of *Chrysanthemums*; he has a fine collection, which were at the end of last week mostly potted into their flowering pots. I never saw anything like the wreck they now present. The pieces I send are weak shoots. Not only are the tops and leaves cut off, but the stems are bruised with pieces of ice, and the stronger plants are in many cases split in two. Yesterday for the first time since Sunday we had sunshine; this caused the few leaves remaining on the plants to droop, as though dry at the root. Doubtless these have partly perished, as the pots were full of ice for quite an hour altogether—a sorry sight for an enthusiastic lover of the autumn queen. All parts of the garden in both places suffered in a similar manner, the ground being strewn with shoots and foliage of all kinds of things. Apples and Pears are also much injured, many of the fruit being cut off the trees. I hear similar reports from other places in the neighbourhood.—J. LYNE, Foxbury, Chislehurst.

[We much regret to know of the damage done by the storm, as evidenced by Mr. Lyne's contribution and the specimens sent. They were indeed fearfully damaged.]

SWANMORE PARK.

THE trees were about to assume their autumnal garb, the flowers of summer were almost gone, and the fields had given fruits for the year, when the writer made his first visit to Swanmore. A more recent journey, undertaken as the foliage of the forest was just becoming green, while yet the nodding Daffodil wafted in the breeze, and before the fields were fully clad in their welcome garniture, to Mr. Molyneux in his Hampshire home showed his charge—the gardens and the farm—changed but happily only for the better. In all the several departments of an estate such as that of W. H. Myers, Esq., M.P., there is a never-ceasing activity in the month of May, so that the arrival was made amid signs and sounds of rural industry. All readers of the Journal will not have visited Bishops Waltham, so reference may be made to the ways and means of reaching there for the benefit of those to whom the future still holds that pleasure.

Some may start from London, others from Southampton, and more from Portsmouth, and from the latter it is easy of access, while the two former are slightly more difficult. From the Metropolis the London and South-Western Railway runs smoothly, swiftly, and pleasantly through all forms of land culture—good and bad—from the garden of the cottager to the domain of the wealthy, past the clean grounds of nurserymen, the broad acres of the farmer, and the stretches of forest and woodland. Look a moment at the various phases as the train speeds on. Just to the south of Surbiton is the home of the *Narcissus* and the *Tulip*, for there are situated Barr's Nurseries, the memory of which will scarcely have become dimmed ere Woking, renowned for its shrubs, is passed, followed quickly by Aldershot with its acres of moor peopled by soldiers. Basingstoke brings to mind the vegetables grown by Mr. Bowerman at Hackwood. Winchester, the birthplace of the *Cottage Gardener* over forty-eight years ago, teems with horticultural associations, while Eastleigh brings us to miles of works belonging to the company in whose carriage we are riding. Here the lines branch for Salisbury, Southampton, and intervening places.

The journey interrupted here is soon resumed for Botley, whence come so many Strawberries in the season, and for Bishops Waltham a change must be made into the waiting train, which soon carries us to the end of our ride, and we alight to receive a hearty welcome from the genial "E. M." Passing the ruins of an abbey, handsome in their decay, amongst which may be seen Wallflowers growing on the wall sides, and we are soon in the old fashioned town just named. It is not very large, and the streets are not particularly wide, but they are perfect Thames Embankments in comparison with the lanes upon which we enter after

leaving it. There were made for one vehicle at a time only, there being steep banks on each side, on to which one is very liable to be deposited by the jolting of the conveyance, for be it understood the roads are not wood paved, any more than they are asphalted. However, the ordeal is safely passed, and we emerge eventually into a main road that would be no disgrace to Macadam.

But the drive through Swanmore Park is better, for it is smoother and flanked by cool grass, and handsome trees are dotted here and there. Some have felt the weight of the storms of March and been blown to the ground, though only a few; the majority bent no doubt before the fury of the gale, but withstood the onslaught, and came out unscathed. The creeper-clad residence of Mr. Myers is left behind, and the home of our host is quickly reached. An old house it undoubtedly is, but none the less a comfortable one, which was thoroughly overhauled and made comfortable by an appreciative and generous employer when Mr. Molyneux added to his duties of gardener the arduous work of steward.

Though it is not possible to go into details regarding the farm work, we cannot refrain from remarking upon the generally excellent condition of the land, and the way in which it is proposed to utilise all available ground instead of wasting the 10 or 12 feet wide margins that have hitherto been left. Mr. Molyneux's education as a gardener will doubtless stand him in good stead as a farmer, for no one in the first named capacity has a better appreciation than he of the importance of the most thorough cultivation, and by the work which is now being carried out on the farm it is apparent he intends, so far as is possible, to extend those excellent principles to that department as well. Everyone who knows him, either personally or by reputation, will wish him well in his new duties, and those who recognise his sound judgment, practical common sense, and unwavering determination have little fear for the result.

Returning now to the horticultural department, a few words may be said of the charming Swanmore House, on all sides of which creepers have been trained, and the effect they produce is singularly pleasing. There are Roses in superb condition, Veitch's Ampelopsis, and many other plants that need not now be mentioned. At the foot of the wall at one end of the house is a splendid specimen of *Choisya ternata*, a shrub which in a suitable position is wonderfully beautiful. The smooth lawns around, the borders, the flowering and foliage shrubs, all bear the impress of careful attention. Many of the trees are fine, especially a very handsome Cedar, while the Pyruses, Magnolias, are extremely effective. Another plant deserving of mention is *Exochorda grandiflora*, which was at the time of this visit clothed with flowers. It is said to be shy in some places, but it gives no evidence of this at Swanmore.

One of the most interesting features of Swanmore is the system of having gardens devoted almost exclusively to one kind of plant. For instance, there is a Pæony garden, containing scores of the best varieties in cultivation, and all in the best of health, which must produce a glorious display when they are in flower. The enclosed garden, with its broad borders devoted to Michaelmas Daisies, is equally as complete; while the newly formed Lillium border is no less admirable. The two latter were of course a long way from being at their best, but it could easily be seen by the strong, clean, healthy growths that later on they would be worth a long journey to see. Hyacinths, Tulips, Crocuses, Snowdrops, and Narcissi planted by thousands in the grass are lovely in the spring months, though but a few Daffodils remained at the time of this visit. Every season for a long term of years bulbs have been planted, and the system is one that might well be adopted in every garden in the country. The mowing of the grass is of course not commenced until the last of the foliage of the bulbous plants is dead, or practically so.

May cannot be termed the most favourable time to see the herbaceous borders, the flower garden, or the vegetable departments—their time of plenty will be later in the year. The mixed borders, however, contained

many plants in flower, while over the gateway into the garden a splendid specimen of *Akebia quinata* diffused its peculiar fragrance. The two hedges of *Berberis Darwini* on each side of the centre walk of the kitchen garden looked very fine, and were a pleasant change from the Arbor Vitæ, Privet, or Yew hedges with which one so commonly meets. Everywhere, in beds and borders, there was a tidiness without any signs of stiffness or formality, and a freedom from weeds that speaks well for the attention given by the gardener and his assistants. The vegetable quarters, with their Potatoes, Peas, Beans, Lettuces, and others, were also in a highly creditable condition.

Under glass the Vines were the best feature, for they are magnificent. From the top of the rod down to the water pipes at the bottom there was clean wood, stout leaves, and handsome bunches, a state of affairs that is very different from those vineries where the bottoms of the canes are almost fruitless. Mr. Molyneux attributes this condition to a thorough

FIG. 101.—MAGNOLIA WATSONI. (See page 532.)

groundwork, secured by taking the rods up gradually, thus securing sound growth the whole length. Nineteen years have the Vines been in, and they are as good now as they were five years after planting. The plants grown are of various kinds, and include many foliage and flowering ones that are useful for decoration complete or in a cut state. Sweet Peas in pots were producing numbers of perfect flowers vying with the hundreds of Rose blooms on the roofs in spreading a delicious perfume. Then there are in frames *Chrysanthemums à la Molyneux* (which means much), and scores of other things which cannot be mentioned in these brief notes.

Fruit out of doors at Swanmore is wonderfully good. The walls are all clothed with trees, but the most interesting section is the orchards of young bush and standard trees. No one need wish to see better trees than these. The wood shines with the glow of health, the branches are disposed so as to admit light and air, and the varieties are of the best. Planting is not done by ones and twos, but by dozens and scores. There are long rows of Worcester Pearmain, Lane's Prince Albert, Benoni, Bramley's Seedling, Warner's King, Lord Grosvenor, and others, amongst which it would be impossible to find a really bad specimen of culture. The roots are practically on the surface, and a mulching of good manure is given every year. The fruits are sent to various markets, where top prices are always secured simply because the specimens are of the best quality and are marketed in a proper manner—that is to say, they are all graded before leaving Swanmore. Buyers, knowing of this, can rely upon the sample being the same in the middle and at the bottom as it is at the top of the package. To these attentions to details Mr. Molyneux ascribes his success in getting such excellent prices.

From the orchards we made our way through fields and belts of trees back to our resting place, passing as we went the hundreds of chickens of which our guide is so proud, and which he expects to grow as well as Chrysanthemums and Apples. The shades of night were falling, and save for the sweet song of the nightingale, there was no sound to disturb the peaceful stillness of this charming Hampshire home. After another look round in the morning the return is made to Bishops Waltham, *en route* not for London but for the Isle of Wight. —H. J. WRIGHT.

FIRST REPORT OF THE WOBURN EXPERIMENTAL FRUIT FARM. 1897.*

THIS book consists of 194 pages, and contains the "Working and Results" of the above establishment, founded by his Grace the Duke of Bedford at Ridgmont in 1894. The report is by the noble Duke and Mr. Spencer U. Pickering, F.R.S.

The ducal house of Bedford holds a highly distinguished position in the annals of British research in agriculture and landed estate affairs, and the munificence of the present head of the renowned family is seen in the Experimental Farm placed at the command of the Royal Agricultural Society under Dr. Voelcker, and in the Fruit Farm supervised by Mr. Spencer U. Pickering, F.R.S. These initials, as everyone knows, imply a person of distinguished talent and meritorious research in the arts and sciences.

The report suggests that the Woburn Experimental Fruit Farm will be carried on on purely scientific principles. This is a departure from established precedent. Science is regarded by many, if not most, cultivators of the soil, as synonymous with theory—always attempting something but showing little that is tangible—useful. Now, at last, we hope to have proved and explained, the sound, solid, and sure foundation upon which has been built the superstructure exemplifying British horticultural art, as seen in its highest aspects, in a manner unrivalled by any other nation in the world.

In the introductory remarks our noble and learned authors state that "The main object of this experimental station is to ascertain facts relative to the culture of fruit, and to increase our knowledge of, and to improve our practice in, this industry. Our object is not to provide a model of a commercial fruit farm, nor to induce farmers to adopt fruit farming instead of agriculture. We believe it is true that fruit farming might be successfully extended in this country, and that a certain, though perhaps a small percentage of those who now find agriculture an impossibility, might be able to gain a fair livelihood by the culture of fruit; but if we are to aid any such extension, it will not be by the direct, or still less by an indiscriminate advocacy of the industry, but by increasing our knowledge of it, both from a scientific and practical point of view, so that those who may embark on it may be able to equip themselves better for their profession than they now can." That is excellent.

The report is divided into two parts. Part 1 treats of the "Description of the Ground and the Experiments," and part 2 of the "Experimental Results." In order to be understood of my readers, I will give a few extracts that will not only be interesting, but convey useful information to readers of the *Journal of Horticulture*, who may not invest in the book (price 5s.), which, however, I strongly advise them to do, so that they may see for themselves to what scientific scrutiny our time-honoured practices are being, and are to be, subjected. But there is nothing to fear; the methods adopted by our most successful cultivators will stand any test that can be brought to bear upon them, and if they can be bettered in any way by all means let science extend its hand and show a better way to increased, more useful, and economical production. Then, and then only, will it do great and substantial good.

"*The Ground and Soil*—The farm consists of a field of 20 acres, situated close to Ridgmont station on the Bletchley and Cambridge line. Soil, sandy loam. The subsoil a bed of clay of considerable depth. Borings have been sunk in two places to 45 feet below the surface without reaching the bottom of it. The ground was all well trenched before planting was done, and repeated forking and hoeing have been necessary to get rid of the weeds, which were very abundant. Throughout the greater part of the field there is a gentle slope towards a brook, which runs along the south-west side of it. The height in feet of various parts of the ground below the highest point is marked on a sketch plan, the highest point being about 15·4 feet above a road by a brook, the distance from this road being 750 feet, and the average slope, therefore, 1 in 49. The brook runs between banks 3 to 4 feet high; it is never dry, and in flood time it occasionally overflows its banks, swamping the lower portion of the ground."

A table of analysis of soil gives the percentages in lime, carbon dioxide, potash, phosphoric acid, nitrogen, and sand, at three different depths—namely, first, 9 inches; second, 9 inches; third, 9 inches, and from five stations, which strike me as singularly interesting and instructive, as for instance:—

Sample. A.	Lime.	Carbon Dioxide.	Potash.	Phosphoric Acid.	Nitrogen.	Sand.
1st 9 inches.	0·36	0·11	0·25	0·16	0·136	58
2nd 9 inches.	1·12	0·45	0·54	0·13	0·088	32
3rd 9 inches.	3·84	2·28	0·73	0·09	0·060	14
† Mean.	1·77	0·94	0·50	0·12	0·094	34

* Eyre & Spottiswoode: London.

† Not given in the Report.

Now if the ground was trenched 2 feet 3 inches deep, down goes the 0·16 of phosphoric acid, and 0·136 of nitrogen—the chief factors of fertility, with the 58 of sand—an important substance as regards the mechanism of soil; and on the top there are 3·84 of lime, 73 of potash, and 14 of sand, 9 inches of "liver" and sterility, for the potash does not come out well without a due proportion of phosphoric acid and nitrogen.

Suppose we mix the whole three together instead of trenching, then we see that a thorough stirring affords a mean of constituents and staple, which mostly return an equivalent in crop equal to, and in some respects better than, a good manuring. If this were carried out with the other remainder of the samples, the difference between trenching and stirring would be even more striking.

"Trenching," according to all authorities, and as understood by practical men, means making a trench not less than 2 feet deep, and in this casting from the next section of equal width a spade depth of the surface soil, then placing the under or subsoil on the top of it. "Bastard trenching" is another thing entirely, and generally very much better in dealing with a ploughed field. In exhaustive experiments in fruit growing, such as those in question, it is to be presumed that both methods are being fully tested, also drained and undrained land, as going literally to the root of the whole matter.

The analyses of soil show a considerable variation, both in constituents and in staples, which are clearly set forth in the plan and references. The field is not a scientifically ideal one; but all the better for that as it will require different treatment so as to suit the varied fruits, necessitate more extended experiments, and result in information adapted to the requirements of the greater number of persons who must of necessity work under very diverse conditions as to site and soil, not one area in a hundred, be it large or small, being "ideal."

Sites relatively high and low, dry and wet, with soils strong and weak, rich and poor—mostly poor—have to be turned to account in the best way they can, and if science can prove by practice the better way for each this will "increase our knowledge and improve our practice," the world being the gainer. A dead level of uniformity might gladden a scientist's heart and make his work easy, but the results accruing would not and could not meet the wants of the majority who have to work under more or less adverse conditions. Experiments conducted on the typical Woburn sand would be greatly limited in their ultimate usefulness.

Having regard, then, to the vital and substantial question of ascertaining facts for affording sound guidance to those who most need it under varying and often unfavourable circumstances, the field at Ridgmont seems to afford excellent scope for attaining the object the Duke of Bedford has in view—"equipping those workers on the land who may embark in fruit growing with the scientific and practical knowledge" which so many lack; and who therefore fail.

Proceeding, the report says that no manure was used at the time of planting. Subsequently artificials were applied, based on an analysis (given in the report) by Professors E. Wolff and J. König, and of which the constituents and quantities are also given; but as there has, obviously, not been time for ascertaining decisive effects, for these we must be content to wait.

In the foregoing I have endeavoured to give the reader an insight into the situation, soil, and principles of nutrition accorded to the trees in the Woburn Experimental Fruit Farm, as these, from a practical point of view, are the greatest essentials. The descriptions of the experiments follow in the report, and are shown on a well-executed plan to a scale of 200 feet to the inch. Altogether there are 672 experimental plots, to which I cannot refer in detail; but there are representations of nearly all conceivable methods, and the whole minutely referred to. Most, if not all of these, however, have been already carried out, some in this and others in different places and countries; but, and this is the great and grand distinction of the Duke of Bedford and Mr. Spencer Pickering's objects and plans—namely, in bringing something of everything and nearly all scattered methods and operations in one field. In this respect the Woburn Experimental Fruit Farm is unique. All hardy fruits, in every form of culture, can be compared with each other under both an identity of and in differing soil and enviroinal conditions.

There are dwarf Apple trees on the Paradise stock under ten different modes of branch treatment, five of root treatment, six of surface soil, ten of different manures, five of amount of manure, five of time of applying manures, fourteen of planting, and five of time of planting, or sixty experiments, with six trees each of Bramley's Seedling, Cox's Orange Pippin, and Potts' Seedling in each experiment. Indeed, there appears to be every form of tree and mode of procedure exemplified on both dwarf and free stocks, besides collections in both forms. We are not surprised that spring planting has answered so well, but one swallow does not make a summer, and it is hoped the planting experiments will be repeated. The effects of pruning and non-pruning after planting are shown in illustrations, and so far all in favour of the former; but in these and other experiments more time is needed for fully testing the results.

Eighty-six varieties of Strawberries are grown for comparison "Farmers' Plots" in fruit trees, bush and standard, are demonstrated and shown by plan, likewise "Growers," and "Cottagers" receive a fair share of attention.

Then come experiments on the arrangement of trees, with the object of ascertaining the respective merits of the different systems in which the same number may be arranged in a given space, as quoted below:

"Each plantation consists of thirty six-trees, twelve Monarch, twelve Czar, and twelve Victoria Plums, surrounded by trees of Rivers' Early

Prolific, so that none of the experimental trees are 'outside' trees on their respective plantations.

"Each plantation represents an arrangement giving 1210 trees to the acre, and therefore every tree has the same amount of space allotted to it."

To demonstrate this our noble and talented experimentors have adopted three systems of arrangement, as follows:—Square: "the neighbouring trees are 1.83 metres (6 feet) in two directions at right angles to each other."

Rectangular.—"In which the distances between the trees in one direction, 2.59m. (8 feet 6 inches), are double those 1.30m. (4 feet 3 inches) between them in a rectangular direction."

Hexagonal or Equilateral Triangle.—"In which the trees form rows inclined to each other at angles of 60° instead of 90° as in the preceding arrangements. The distance between the trees in these rows is 1.99 metres (6 feet $6\frac{1}{2}$ inches)."

As these arrangements are not clearly shown by diagrams, I have considered that it may be useful to young probationers if they were given in the *Journal of Horticulture* with a few observations.

Square (fig. 102, A). To get this we form a figure with four sides at the corner of the plot to be planted with trees, each side of the distance they are to be apart, and each angle formed by the lines intersecting at a right angle. It is 6 feet square (a), and in the centre of this put in a peg—a station for the first tree. This will be 3 feet from the side and end of the plot, and a radius of that distance embraces a circle 6 feet in diameter—the space at the command of the individual tree, which is less than that of the square = 36 square feet.

Rectangle (B). The length (8 feet 6 inches) is measured from a corner of the plot, then the breadth (4 feet 3 inches) from the starting point at a right angle, and from the long leg and the short bisect the radius of the two distances, and have a rectangle (b)—a figure twice as long as wide, and its four angles right angles. Its centre is the station for the first tree. The dimensions of the figure are 36 feet 28 inches, but of this the tree can only command the area enclosed in a circle 4 feet 3 inches in diameter, for Nature will assert its supremacy—the tree grows equally all round from its stem in spite of either science or practice, and can only spread 2 feet $1\frac{1}{2}$ inch in the direction of its nearest neighbour, equally anxious to make the most of the advantages present. Therefore, the rectangular placed tree soon becomes pinched on two sides for room, whilst on the other two it may grow out 4 feet 3 inches without hindrance.

The rectangular method is the sheltering-wind system of gardeners, and much approved by some, as it admits of cropping the unoccupied space between the rows of trees, with other advantages, such as shelter, obtaining and retaining the sun heat, which means earlier or later, as the case may be, and, in some cases, better produce. The trees get plenty of sun and air, more than by either the square or equilateral triangle modes, always provided the between crops are low, kept away from the trees, and these not allowed to meet in the rows so as to form a hedge, thus losing half of each tree.

Equilateral triangle (C). This figure consists of three sides and angles, all equal, and the points correspond to stations for trees. To form it, proceed as in forming the square, for the equilateral triangle is only the half of an equilateral rhombus—an oblique square, but have the base line 5 feet 6 inches—the distance between the rows, and the perpendicular 6 feet $6\frac{1}{2}$ inches—the distance for the trees in the rows. Its centre is the station for the first tree.

The trees by the equilateral triangle system are 6 feet $6\frac{1}{2}$ inches from each other, those by the square plan 6 feet, and by both methods the trees are equidistant. On the "square" the trees have the same space in the rows as between them, but those on the "equilateral triangle" are not so far apart between the rows as in them, neither horizontally nor obliquely. The trees on the rectangular system are really only 4 feet 3 inches apart, as half the space is unoccupied so far as the trees can make use of it.

In Nature—it is the whole art—the trees grow upward and outward equally. It is the same with well managed ones, so that each tree claims, as far as it can, its share of light and air. The "square" has more of these essentials than the "equilateral triangle," and the

"rectangle" twice as much as the square. This is demonstrated by the space outside the circles.

On the square method four trees occupy 144 square feet, and the thirty-six trees that number of square yards, thus forming a square of six ranks every way—the Greek phalanx—the best arrangement for men and trees.

By the rectangular system four trees stand on ground 17 feet long and 8 feet 6 inches wide = 144 $\frac{1}{2}$ square feet, and the thirty-six require a parallelogram 51 feet long and 25 feet 6 inches wide = 144 $\frac{1}{2}$ square yards.

On the equilateral triangle mode the area within the lines forming it is 18 feet 28 inches, but every tree does not stand in its centre, but in an equilateral rhombus—a figure of two equilateral triangles; therefore each tree has the better side of 36 square feet at its command, and every four trees advantage of something over 144 square feet. The thirty-six trees in six rows require an area in the form of a parallelogram of 51 feet long and 25 feet 6 inches wide = 144 square yards $4\frac{1}{2}$ square feet, but this must not be a rectangle, or a tree will be lost, or a station for one, in every other row, therefore the trees cannot be got in, being three too many. If the figure be a rhomboid—an oblique rectangle—they will fit in exactly. This is easily formed, either on paper or the ground—at least, if it cannot be done in theory it cannot be in practice.

I have shown the equilateral triangle system on the "square," but by taking forward any of the oblique lines, so as to provide stations for six trees, a rhomboid may readily be constructed. The loss of trees or stations on the square is shown at d. Every four trees form the angles of a rhombus one way, and the other "diamond"—that for the glorious Jubilee. Six trees (d) equidistant from and around a central one (e) correspond to the angles of a hexagon, hence the system is sometimes called the hexagonal. Albeit, the tree in the middle renders the whole thing septuple, which is exactly what it is when one has to plant trees on this little-used system.

I had intended to complete the critique of the "Working and Results" in a much less article than this has run into, but I found the whole so interesting, and the tree arrangement so intricate, that I got lost in diagrams and numerals, and in getting in and out considered the matter might as well be traced in as clear a manner as possible. The scale is 16 feet to 1 inch, so now, Mr. Editor, let young gardeners have a little educational exercise in working the whole three systems out to thirty-six trees, and in that way, among others, the Woburn experiments will do good. "Results," therefore, must stand over for another article, if room for it can be found in the *Journal of Horticulture*.—G. ABBEY.

FIG. 102.—METHOD OF ARRANGING TREES.
A, square; B, rectangle; C, equilateral triangle.

INSECT INVASION.

I AM pleased to learn that our old friend the Persian gentleman, as "Wiltshire Rector" once termed "Y. B. A. Z.," is not yet extinguished, and trust it may be many years before such a loss befalls us. It is to such as he who, after a busy life in a profession demanding the keenest observation of cause and effect, is left in its eventide with a comparative amount of leisure, possessing abilities of no mean order and great energy, also a thorough love for things horticultural, without the fads and wrong notions of the average professional gardener, that we must look to for help in solving many of the difficult problems which still surround us.

"Light periodical fumigation" for aphides is a useless extravagance, not unattended with danger if tobacco paper is used, and needlessly curtailing the enjoyment of those for whom the houses are kept going. There are several preparations now that can be used with such certainty and safety that the old haphazard plan need not be resorted to. Among these are the XL Vapouriser and Hughes' Vapour Rolls. By measuring the capacity of the house, stuffing up any large openings that may be there, and following minutely the vendor's instructions, you may with certainty kill every aphid with one operation without damaging the tenderest Fern frond or the leaf of a *Humea elegans*.

Whatever may have been the habits of the ancient aphides, the modern ones do not go the roundabout way of laying eggs except for preservation during winter, so that one properly conducted fumigation or vaporisation clears your house entirely, and in my experience one operation has occasionally sufficed for a whole season, even with a house of Roses.—WM. TAYLOR.

DURING the last few days, without the cognisance of either "W." or myself, there must have been a telegraphic or telephonic wire between us. At times certainly there has been electrical tension in the atmosphere, but that would scarcely account for the story as it stands. It must have been something more tangible—and, truly, there it is—it must be the bond and sympathy of "Our Journal!" Hang the differences of opinion, say I, if they after all only bring us closer together; if they but make us feel that we are co-workers, some in a very humble way, like "Y. B. A. Z.," others, like "W.," practical, inured to work, and successful in it.

Is it not a strange coincidence—reading like some incident in a romantic novel—that "W." should quite accidentally stumble on the early days of my cognomen and the visit of my early friend, and in those days our Journal's friend—"Wiltshire Rector?" How the words carry us back! It is several years since I heard anything of my old friend, and it is a record of the past. But the strange portion of the story is this—that whilst our friend "W." was, shall I say, standing aghast at this demolition of his "Young Bachelor" theory, and ruminating thereon, I too was raking up the ashes of memory and penning

them to "our Journal" in order that the many readers might have the pleasure of reading a letter from the then facetious editor, which was the sequel to that visit of "Wiltshire Rector's."

That letter I treasured, and have kept ever since, and with a few remarks it was forwarded for the inspection of the present wearer of the editorial mantle to see and to print. *En passant*, I may recall my own despair at the appearance, not the flavour, of the Malay chicken, which did not look as well as I hoped, or as that breed generally does on the table; in fact, it was to me a case of the Irishman's pig which, when killed, did not weigh as much as he expected—and he never thought it would!

The old Editor's letter, printed after the appearance of "Wiltshire Rector's" pleasantries, runs thus:—

171, Fleet Street,
February 4th, 1865.

Salaam Do,—May your shadow never be less, O Ybaz! When you next sacrifice a Malay or a Bramin to propitiate a Priest of the West may we be there to partake of the savoury offering.

We beg permission to place before your footstool a chit from another son of the West—be gracious to him, and reply by the public burkaru (vulgar, post).

Wishing you nothing but sunshine—and no end to your blessings to and from "our Journal." I bend lowly as—ONE OF THE FAITHFUL.

After all this, it is perhaps but fair to enlighten any who care to know why I adopted "Y. B. A. Z." as my signature. In days long since gone by I was hating myself whether I would, or *could*, write anything that would be either useful or interesting to "our" readers. On the point of giving up, the thought came, "Why be a zero?" I dashed off my thoughts, and not liking the aspect of "Y. B. A. O.," I took the first letter of zero as the final, and now the murder is out. After all, "What's in a name? A Rose by any other name would smell as sweet." It might, possibly; but I fancy were it changed the plant would be more thorny still, and some of them are thorny enough already. But who, in this Diamond Jubilee year, when it is suggested that everyone should wear a Rose on the commemoration day, would think of changing the name?

Just a word of thanks to friend "W." Evidently he feels certain that milder doses of fumigation will destroy the eggs of aphides. I have been groping in the dark over this, but had nearly arrived at this conclusion, except as to the mildness of the dose, but now, as far as inside the house goes, I do not mean to have an aphid visible. It is, however, no wonder if we amateurs do make mistakes as to watering, air, and routine. It is practice that makes perfection, and here, of course, the practised gardener beats us; still, once every now and then solace comes to us, and I, in common I expect with most amateurs, enjoy it when it occurs, I mean the pleasure of beating the practical gardener in open competition, a pleasure which has, though very rarely, been the lot of him who still is the learner.—Y. B. A. Z.

[It is quite true that the characteristic letter of "One of the Faithful" (the late genial Mr. G. W. Johnson) was received by us last week, as also was that of Mr. W. Taylor; but both these letters arrived after our pages were filled, with "W.'s" narrative and "discovery" in them. It seems that the minds of three persons were directed (practically at the same time) to the same circumstance, which occurred more than thirty years ago. This would not be singular in the case of those who remembered the episode, but it was somewhat remarkable that the third, who had no knowledge of it, should, when searching for something else, take a volume out of a long series (nearly 100), and open it on the very page containing an article headed "Y. B. A. Z.," probably the only article so headed in the 50,000 pages bound in the series, and this just at the time when he was interested in the cognomen, and seems to have been trying to solve the problem involved in it. Let us hope he will be happy now. As these are commemorative days, we should not be surprised to hear of "Y. B. A. Z."-ero, who has a heart even many degrees above freezing, considering the sacrifice of another Malay (if he have one left), in order that the telepathic trio may have a celebration of their own. We feel certain they would be "friends at once," and then might again be proclaimed by the host the ancient formula, "There is the bond!" pointing to "our Journal." He would not be pronounced a Zero by the guests, who, we may expect, would at once propose and pass an amendment, "That 'Z' be struck out, and 'H' take the lead in its stead."]

NEW CODLIN MOTH SPRAY.—Professor R. C. Kedzie of the Michigan Agricultural College claims for the following spraying mixture that it is more reliable than Paris green, that it does not burn the foliage of trees, and that it costs considerably less. It is not patented, and here are his directions for making it. Boil 2 lbs. of white arsenic and 4 lbs. of sal soda for fifteen minutes in 2 gallons of water. Put into a jug, label poison, and lock up. When ready to spray, slake 2 lbs. of lime and stir it into 40 gallons of water, adding a pint of the mixture from the jug. The mixture in the jug will be enough for 800 gallons. These 800 gallons will require 40 lbs. of lime. Its advantages over Paris green are as follow: It is cheaper, and the ingredients can be readily procured; it is easily prepared and kept ready; it will keep for any length of time; it is uniform in strength; it does not injure the leaves of trees or plants; it colours the leaves white, showing how evenly it is distributed. This spray mixture comes well endorsed, and is worthy of a fair trial. Personally we know but little of its action or efficiency, and we would be pleased to learn the results from those who experimented with it.—("California Fruit Grower.")

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL, JUNE 15TH.

For the first time since the great Temple Show the Committees met at the Drill Hall. The corresponding meeting of previous years has been small; but this was by no means so, for the hall was nearly full. Orchids were not numerous, neither were fruit nor vegetables.

FRUIT COMMITTEE.—Present: T. Francis Rivers, Esq. (in the chair); with Rev. W. Wilks, and Messrs. J. Cheal, J. H. Veitch, G. W. Cummins, A. F. Barron, Peter Veitch, J. Smith, T. Fife, H. Balderson, G. Wythes, G. Sage, T. G. Miles, A. Dean, F. Q. Lane, and J. Wright.

Several Melons were sent, but none reached the standard of quality entitling to a certificate. One from the Isle of Wight was quite rotten; a promising variety from Mr. Wythes not quite ripe; one from Dropmore decidedly over-ripe; several from Mr. Bishop, Westley Hall, very handsome; and one of them, Westley Defiance, a large, oval, well netted green-flesh, of beautiful appearance, not quite ripe; desired to be seen again.

Mr. Miller, gardener to Lord Foley, Ruxley Lodge, sent a small collection of fruits comprising Grapes, Cherries, and very handsome Royal Sovereign Strawberries; a bronze medal was granted. Mr. W. Palmer, Andover, sent good dishes of Peas of Sutton's A1 and Laxton's Gradus.

Several Cabbages were sent from Chiswick, and for two of them, Veitch's Earliest of All from Messrs. R. Veitch & Sons, Exeter, and Sutton's Earliest, Messrs. Sutton & Sons, Reading, awards of merit were granted. These were much earlier than any others, both ready May 15th. The first-named very dwarf and compact; the second mentioned somewhat larger, a beautiful conical or pyramidal variety with tender-looking hearts.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and Messrs. J. Fraser, A. Deah, J. Hudson, G. Nicholson, G. Gordon, J. Jennings, C. J. Salter, C. Jeffries, J. D. Pawle, C. E. Pearson, C. E. Shea, H. J. Jones, J. Walker, E. Beckitt, H. J. Cutbush, C. Blick, H. Turner, G. Paul, R. M. Hogg, and E. Mawley.

The Cannas sent by Messrs. H. Cannell & Sons, Swanley, made a bright display and included the majority of the leading varieties in cultivation. The same firm also sent Gloxinias Amiable and Sherlock Holmes. Messrs. W. Paul & Son, Waltham Cross, staged a few plants of the beautiful Rose Enchantress. Very interesting were the foliage and flowering plants sent by Messrs. J. Veitch & Sons, Limited, from their Coombe Wood nurseries. There were Viburnum Mariesi, Olearia stellulata, Azalea Mikado, Veronica prostrata, Nymphæas in variety, and several others. The exhibit from Messrs. Kelway & Son, Langport, of single and double Pæonies and Delphiniums was very imposing and of great interest.

Hardy herbaceous plants from Mr. M. Pritchard, Christchurch, were varied and beautiful. There were amongst others Pæonies, Centaureas, Irises, Spiræas, Aquilegias, Heucheras, and Achilleas. Messrs. R. Wallace and Co., Colchester, staged a collection of Spanish Irises, Liliums, Brodiaeas, and Calochortus, all of the best quality; Messrs. Dobbie & Co., Rothesay, N.B., exhibited Pyrethrums in considerable numbers, as well as Pelargoniums with Dahlias of good quality. Very charming was the exhibit of garden Roses sent by Messrs. G. Cooling & Sons, Bath. The diversity and excellent quality made the exhibit exceedingly interesting.

Strikingly beautiful were the Pæonies from Messrs. J. Veitch & Sons. There were dozens of distinct varieties, ranging from pure white to the deepest crimson. The whole of the varieties were double. Veitch's hybrid Aquilegias were very fine. Mr. C. Dymott, Millbrook Road, Freemantle, sent plants of Pelargonium Harry Dymott, a seedling of promise. Delphinium Belladonna, Potentillas, and Pæony albiflora carnea came from Mr. Gifford, Tottenham, and hardy flowers in variety from Messrs. A. W. Young & Co., Stevenage.

Messrs. Paul & Son, Old Nurseries, exhibited Pæonies and garden Roses in fair numbers and of splendid quality. The same firm also staged a small but very interesting collection of plants suitable for the rockery. Messrs. J. Peed & Sons, Norwood Road, S.E., sent a group of Carnations, comprising Miss Measures, Cole's Improved, and Mr. R. H. Measures. Messrs. F. Cant and Co., Colchester, staged garden Roses in their well known excellent style. There were Paul's Carmine Pillar, Austrian Copper, Mignonette, Janet's Pride, Lord Penzance, Moss, Austrian Yellow, and others.

Messrs. Barr & Son, King Street, Covent Garden, were represented, as they usually are, by a collection of hardy plants, including Irises, both German and Spanish, Delphiniums, Pæonies, and others. Mr. B. Ladhams, Shirley, Southampton, sent Pinks of fine quality, with a few beautiful Campanulas. Violas in variety, Pyrethrums, Irises, Papavers, Lychnis, and Geums were included in the stand arranged by Messrs. J. Cheal & Sons of Crawley.

Quality was conspicuous in the Carnations sent by Mr. C. Blick, gardener to Martin R. Smith, Esq., The Warren, Hayes. The varieties included Queen of Sheba, Barras, Cecilia, Quentin Durward, Wanderer, Helmsman, Perséus, Comedy, Cygnet, Amazon, Mrs. Tremayne, and Sappho. Mr. Chas. Turner, Slough, also sent fine Carnations, beautiful amongst which were Mrs. S. Bouverie, The Gift, Goldmine, May Queen, and Knight Errant.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, De B. Crawshay, H. Ballantine, F. Sander, H. Williams,

W. H. White, E. Hill, J. T. Gabriel, A. H. Smee, W. H. Young, H. J. Chapman, S. Courtauld, J. Douglas, and T. B. Haywood.

The only exhibit of Orchids of any size was that from Messrs. J. Veitch and Sons, Ltd. Not only was this admirably arranged, but it contained nothing but plants of the best quality. Amongst the *Cypripediums* were *Curtisi*, *Lawrenceanum*, *selligerum majus*, and *superbiens*. *Lælias* were also splendid, while *Odontoglossums*, *Dendrobiums*, *Sobralias*, and *Masdevallias* lent pleasing variety (silver Flora medal). Mr. W. H. White, gardener to Sir Trevor Lawrence, Bart., sent a few Orchids, including *Vanda Agnes Joachim*, *Phalaenopsis grandiflora*, and *g. odorum Augusti*.

Mr. W. H. Young, Orchid grower to Sir Frederick Wigan, Clare Lawn, East Sheen, sent a few Orchids, of which *Lælio-Cattleya Orphanum*, *Cattleya Mossiæ*, Mrs. Egerton Grey, and *Miltoniæ vexillaria candida* were conspicuous. Messrs. F. Sander & Co., St. Albans, sent three plants only—namely, *Lælio-Cattleya Empress of India*, *L.-C. Our Queen*, and *Cattleya Mossiæ Empress of India*.

CERTIFICATES AND AWARDS OF MERIT.

Calochortus Gunisoni (R. Wallace & Co.).—A beautiful pure white form of high quality (award of merit).

Carnation Barras (C. Blick).—The petals of this variety are superb. The colour is scarlet crimson, and the flower is sweetly scented (award of merit).

Carnation Cecilia (C. Blick).—A magnificent flower, unfortunately lacking fragrance. The colour is yellow (award of merit).

Carnation Helmsman (C. Blick).—A pure white, of perfect form and large size. The flower is Clove-scented, and the calyx shows no tendency to split (award of merit).

Cattleya Mossiæ In Memoriam Richard Curnow (H. Low & Co.).—A magnificent *Mossiæ*. All the organs are very large and substantial (award of merit).

Cattleya Mossiæ Empress of India (F. Sander & Co.).—A superb form. The colour is purplish rose in the sepals and petals, and the lip crimson purple (award of merit).

Cedrus atlantica aurea (J. Veitch & Sons, Ltd.).—This golden-tip variety of *atlantica* is very charming (first-class certificate).

Celmisia Monroi (J. Veitch & Sons, Ltd.).—A hardy plant with Pine-like leaves and large white Marguerite-like flowers (first-class certificate).

Delphinium Clara Stubbs (Kelway & Son).—Very bright blue is the colour of this variety (award of merit).

Delphinium Sir John Forrest (Kelway and Sons).—The flowers of this are rich blue purple and very large (award of merit).

Doryopteris nobilis Duvalli (J. Veitch & Sons, Ltd.).—A very handsome-leaved Fern with deep green foliage (award of merit).

Escallonia langleyensis (J. Veitch & Sons, Ltd.).—Very free flowering is this hybrid. The blooms are bright rose in colour (award of merit).

Iris germanica maxima (T. S. Ware).—A fine variety, of which the standards are light and the falls dark blue (award of merit).

Lælio-Cattleya Our Queen (F. Sander & Co.).—This is a lovely bi-generic hybrid, of which the parentage is not known. The sepals and petals are white, with the most delicate blush suffusion. The lip has a white margin round the large patch of crimson. The throat is yellow (award of merit).

Lælio-Cattleya Empress of India (F. Sander & Co.).—The parents of this were *Lælia purpurata Brysiana* and *C. Dowiana*. It is of great beauty. The sepals and petals are deep purplish rose, and the lip velvety crimson maroon (award of merit).

Odontoglossum crispum Crawshayanum (De B. Crawshay).—The rather narrow sepals and petals of this variety have fine chocolate blotches on the white ground (award of merit).

Pink Albina (F. Gifford).—A white variety with Clove-scented blooms. The calyx seems inclined to split (award of merit).

Rose macrophylla (Paul & Son).—A charming flower of soft rose shade (award of merit).

Vanda Agnes Joachim (W. H. White).—A lovely hybrid, resulting from a cross between *V. teres* and *Hookeriana*. The petals and upper sepals are delicate rose, and the lower sepals white. The lip is purplish rose (first-class certificate).

LIST OF AWARDS.—Floral Committee.—Silver Flora medals to Messrs. J. Peed & Son, J. Veitch & Son, Ltd., R. Wallace & Co., Kelway & Son, M. Pritchard, and H. Cannell & Sons. Silver Banksian to Messrs. Paul and Son, S. Cooling & Sons, Dobbie & Co., F. Cant & Co., B. Ladhams, and J. Cheal & Sons. Bronze Banksian to Messrs. A. W. Young & Co.

A BIG VINEYARD — A recent issue of the New York "Fruit Trade Journal" gives an account of a newly planted Grape fruit grove in Florida, said to be the largest in the world. The soil is virgin hummock land, which, within a year, was cleared of massive Oak and graceful Palmetto trees, and comprises above 200 acres. The tract extends half a mile along the Manatee River, and is more than that distance in depth. The land was thoroughly prepared by experienced cultivators of Grape fruit, and 20,000 budded trees of the best varieties have been planted.

THE YOUNG GARDENERS' DOMAIN.

SUMMER BEDDING.

I HAVE often noticed in my experience how many gardeners have the same designs in the flower garden year after year, without any perceptible change. Let us try and alter this everlasting sameness, and by tasteful arrangement have something fresh every season, and always better than the last. I remember well the first situation I had; the flower garden was a model of neatness and cleanliness that I have not seen equalled since; its only fault was in being always the same. Year after year the same plants and designs appeared, as though the gardener had reached a certain point in horticulture and dare not move another step.

During a visit to my old friend last summer, after an absence of some years, we went to view the flower garden; it seemed to me but yesterday that I had been there. Yes, there it was, the same well-kept garden with the beds of *Calceolaria Golden Gem* edged with dark-leaved Beet; *Vesuvius Pelargoniums* with an edging of the *Lobelia*; beds of *Ageratum Little Cupid* with a golden edge of *Pyrethrum aureum*. And how well I remember that design in the Maltese cross beneath the drawing-room window: there is the large *Agave americana* in the centre, surrounded by Mrs. Pollock *Pelargonium*, two of the sides filled with *Tropæolums*, the other two with *Verbenas*. It was a splendid display for a stranger to see, but how tiring to the eyes of those who have seen it for so long. It will be changed this season, as my dear old friend, the kindest master I ever had, has gone to join the great majority.

There is a plan I have always followed, and I advise all young gardeners in the domain and out of it to do the same, and if they derive as much pleasure from it as I have done my note will not have been in vain. I always make it a rule to draw a plan of the flower garden every season, no matter where I am stationed, and note down how every bed and border is arranged. Then in the long nights of winter I bring out these plans, draw the outlines of another, and fill in the beds from imagination with what is thought will have a good effect; then compare it with the real plan and see if I have made any improvement.

For instance, here in the rough sketch before me is a large diamond-shaped bed; at the time of drawing, the bed was filled entirely with yellow *Calceolarias*, and after a spell of wet weather they looked anything but ornamental. How would it look arranged in this manner? In the centre one *Ricinus Gibsoni* with four more arranged diamond shape a good distance from it; intersperse some *Hyacinthus candicans* and *Lobelia cardinalis*; round these run a belt of *Salvia patens*, followed by another of *Begonias*, and then finish with an edging of *Dactylis glomerata aurea*. I could suggest more methods, but space forbids.

Before I finish let me advise that in the summer garden foliage and flowering plants be intermixed, so that one may support the other in wet weather and in dry. Dig well, manure well, put out plants few and good rather than numerous, drawn, and weakly. Note the defects of this year's arrangements for correcting another season. Keep your ears open when visitors come, and your eyes when you go visiting, and so obtain and lay up a store of knowledge for use hereafter.—J. C., Lancashire.

[Very good advice, and worthy of being kept in remembrance.]

GROWING MELONS IN FRAMES.

THOUGH now superseded by the modern and more excellent method of cultivation in hothouses, Melon growing in frames is still carried on on a very large scale during the favourable months of the year—viz., May to September. Mention is made of these months because in most gardens the frames intended for Melons are occupied until the end of May by bedding plants, early Potatoes, or other requisites, and also because Melons remaining in frames after the end of September are mostly deficient in flavour. As soon, however, as the frames are clear they should be made ready for the reception of the Melons without delay.

Make a bed of fermenting material such as horse stable refuse and tree leaves, large enough to project 2 feet beyond the frame on all sides, and 3 to 4 feet high; place the frame thereon, and build up the 2-feet walls or linings to the top of the lights to allow for sinking. In the case of walled pits material will, of course, only need to be placed inside.

Place in each light one or two mounds of about a barrowload each of the following compost:—Good retentive loam eight parts; brick rubble, broken small, one part; soot and bonemeal one part, the top of the mounds, after sinking, being about 15 inches from the glass. Leave the whole until the heat declines to about 80°, when the plants may be put out. Seed sown singly in 2-inch pots the last week in April and the first week in May in the Melon or Cucumber house, the plants being gradually hardened, will produce sturdy plants with four or five leaves by planting time.

In planting Melons always raise the collar of the plants well above the soil in order that water may easily drain away from the stems, otherwise canker may occur, to which fungoid disease Melons fall an easy prey. It may be prevented by placing around the stem at planting time a few pieces of charcoal, which absorb superfluous moisture, also at the same time place a ring of lime around the plants, 9 inches from them, as a guard against slugs. Should canker show itself, promptly rub the affected parts with freshly slaked lime. Given a good watering at planting time the syringe will suffice for the next fortnight.

As soon as the roots have taken hold of the new compost top the plants, which will result in some four or five growths from the axils of the leaves. Select two in the case of two plants being placed in a light, four growths in the case of one plant only, and train to the four corners of the frame. When about a foot from the corners top these growths, the result being numerous laterals, from which we may expect to get our fruit; should these, however, fail to show fruit after the second leaf top them, when the sub-laterals near the stem will be sure to produce flowers.

Another method is to allow the leader to run to the end of the frame before topping it, and taking the fruits from laterals produced from the main stem. Both methods are good. Before the flowers open give a liberal watering, which will suffice to carry the plants over the setting period. Maintain a dry atmosphere whilst the plants are in flower. If the growths were well selected in the first place no difficulty will be experienced in having sufficient fruit-bearing flowers open at one time to produce a crop. These should be fertilised just before noon by pollen applied to the stigma from the staminate flowers, and top the laterals two leaves beyond the fruit.

It is important that the whole of the crop be, if possible, set at the same time, as if one or two fruits commence swelling before the rest they are sure to take the lead, and the others will either shrivel, or make at the best but poor specimens. In such a case it is better to sacrifice one or two early fruits, and retain a later crop all of uniform fruits. When the fruits are swelling freely thin to the required number, leaving such as are a good distance from the collar of the plants, placing each one carefully on an inverted flower pot.

Water will be required much more frequently when the fruits are swelling, always giving it in a tepid state, and in sufficient quantity to penetrate the whole mass of soil. Weak liquid manure at each watering will help the fruits to attain a large size; it must be discontinued, however, when the fruits commence ripening.

Ventilate carefully, providing a "chink" for air, if possible, before the sun has reached the frames, in order to dry the fruits before the sun can do any harm. When it is seen the fruits are commencing to net air must be admitted more abundantly, leaving a chink on all night; discontinue syringing now, and gradually withhold water from the roots, giving only sufficient to prevent the plants flagging. Should the fruits show signs of cracking, the laterals bearing them may be partly severed to check the flow of sap. The flavour of Melons is much improved by placing them in an airy fruit room about three days before sending to table.—YOUNGSTER.

A SHORT ACCOUNT OF THE CULTIVATION OF DENDROBIUMS.

DOUBTLESS some readers will wonder why I have placed a "short account" at the head, but to go into all the minor details of the cultivation would fill several columns of this Journal.

The method of cultivation differs according to the species, as some of them require a higher temperature, both to mature their growths, and to flower them in, than others. The following "short account" refers to the "mobile" section.

If a start is being made with imported bulbs, first hang them up in a warm, moist house, in a position shaded from the sun. An ordinary plant stove, with a temperature ranging about 70°, will do for them. If they are syringed three or four times during the day, the young roots and growths will soon begin to show themselves. When these appear, the plants may be placed in either pots, pans, or baskets, the latter being the more suitable. Whatever receptacle is used should be thoroughly clean, and as small as possible, according to the size of the plant.

Fill them three parts full of crocks, and over the crocks place a layer of sphagnum moss. The material for potting should be fibrous peat broken into lumps, charcoal, and fresh sphagnum. It is not necessary to mix them previously, but the different kinds may be placed in the pot separately as required. The plants should be placed on a cone above the rim of the pots, and great care must be taken not to injure the young roots and growths that are just forming.

Water must be sparingly applied until the roots have got hold of the compost, and then more copiously as the growth advances. It is very dangerous to allow them to become dry. Rain water heated to the temperature of the house is the most suitable for them. If dipping the plants is resorted to, care must be taken that they are not plunged below the base, or the young growths are liable to be injured.

During the growing season they may be placed as near the glass as possible without coming in contact with it, so that they may obtain plenty of light, but they must be shaded from the bright sun. Syringing frequently between the pots is beneficial, but if the plants are syringed heavily the water will lodge in the nodes and cause the leaves to turn yellow. The paths of the house ought to be kept well damped, and if the pipes are fitted with evaporating troughs these should be kept filled. Occasional fillings with weak liquid manure is beneficial to the plants.

When the growth is completed water must be gradually withheld, and the plants arranged in a cooler and drier atmosphere, allowing them abundance of air and full exposure to the sun, so that they may complete the ripening of the growths. Water must not be withheld altogether, but enough given to prevent shrivelling. After the growths are fully matured a few plants may be placed in a gentle heat to produce early flowers, giving them a small quantity of water, or they will push forth growths instead of flower spikes. By placing a few in heat at different periods a succession of flowers may be had from December to the end of March.

After the plants have ceased flowering, they may be repotted, using

the same material as mentioned for those imported. The main point when potting is to remove them out of one pot into the other without injury to the roots; and this done by breaking the old pot or pan into small pieces. Each piece should be removed separately, allowing those only to remain which have roots adhering to them, and these will help to serve as crocks. In the case of baskets, the old ones should not be removed, but placed in the larger size intended for the plant.

If more plants are required they are easily obtained by division or by cutting off some of the pseudo-bulbs after flowering and laying them in pans filled with sphagnum moss. If these are kept moist they will soon commence making growths at the nodes, and when large enough to be removed may be placed three or four in a 5-inch pot.

Red spider is the worst enemy of the Dendrobium, and when the pest appears the leaves should be sponged with a weak insecticide.—ELVEDEN.

HARDY FRUIT GARDEN.

Strawberries.—The copious rains have improved the prospects of the Strawberry crops. Plants, however, swelling good crops of fruit will be greatly assisted by applications of water or liquid manure. The latter stimulant is especially suitable to apply after the ground has been moistened by rain, because the soluble food principles contained therein will be, when combined with the soil moisture, readily appropriated. Should a dry period set in as the fruit is swelling clear water may be freely given, followed by liquid manure. When it is not available the liberal waterings over the manurial mulching will carry down to the roots beneficial sustenance. Where the mulching material is not of a character to keep the ripe fruit clean fresh straw should be laid down, this either being in long lengths or cut very short.

Propagating Strawberries.—Early propagation is desirable when it is necessary to establish beds to produce a fair crop the next season. A few of the best runners from each fruiting plant may be selected, and the first or best plantlet preserved for rooting into a suitable medium. The methods adopted for insuring well rooted plants are the employment of small pots or squares of turf.

When pots are used, those 3 inches in diameter are the handiest. Press into the bottom a piece of fibrous turf. Fill up the remaining space with good rich material composed of loam and decomposed manure. Partly sink the pots into the ground at convenient places between the rows. With a hooked peg or a stone secure in each pot a strong plantlet just emitting roots. Cut off the growths beyond, also all the remaining runners on the parent plants which are not required.

The turf system requires that small turves about 2 inches thick and square, should be cut while the grass is fresh, though if long it may be cut in closely. If the weather is dry soak them well in water or liquid manure. Take out a small trench between the rows of plants if convenient, or sink the squares in the soil at any suitable point, placing them grass side downwards. Hooked wire or wooden pegs must be employed to attach the plantlets firmly until roots are emitted. Stopping the growths beyond the plantlets, and the removal of superfluous runners must be attended to. The young plants ought to have every facility for becoming strong and well rooted, which they will do if not allowed to be crowded with weeds and a rank growth of runners. During the prevalence of dry periods water must be regularly supplied. Those in pots will specially need attention, sometimes requiring it twice a day.

Wall Trees.—Thinning Fruit.—Give the final thinning to Apricots, Peaches, and Nectarines if the fruits are so thickly placed as to require the removal of some. Select the largest and best placed for retaining, leaving the fruits finally 5 to 8 inches apart, according to size of variety and vigour of trees. A little thinning may also be given to Apples and Pears, removing all but the best fruits on a spur. The final thinning of these may be carried out later.

Syringing and Watering.—A moist condition of the soil about the roots and frequent syringing of the foliage in dry warm weather will tend to keep red spider and aphid in check. Occasional applications of liquid manure to weakly trees, or those bearing good crops which may require assistance to finish well, are desirable.

Laying in Shoots.—Attention given systematically to laying in the reserved young growths of Apricots, Peaches, and Nectarines is well repaid by the better appearance of the trees, and the facility with which abundance of light and air can reach the young growths. The fruit also benefits largely because the resources of the trees are not drained by superfluous shoots. Growths that cannot be laid in, and which it is not advisable to cut out, shorten back to the third leaf to form spurs, subsequent growth from the upper buds of these being pinched at the first leaf.

FRUIT FORCING.

Peaches and Nectarines.—Early Forced Trees.—The trees must now have plenty of air, ventilating the house to the fullest extent after the fruit is gathered, removing the roof lights; in addition to ventilating fully, the border should be frequently damped and duly watered, so that no check is given likely to induce the premature ripening of the wood and foliage. Laterals encourage root action, but they must be stopped to prevent overcrowding, otherwise some lateral extension is desirable as a safeguard against the wood and foliage maturing too early. All shoots that have borne fruit, and which are no longer required, should be cut away to the growths originated from their base for next year's bearing.

Houses with the Fruit Ripening.—The trees started early in February have the fruit advanced for ripening, and this must be kept dry. With a view to prolonging the season of fruit, fire heat may be discontinued, unless the weather be unusually cold, and air admitted freely by day and night, maintaining adequate moisture at the roots. Where it is not wished to retard the fruit, maintain a night temperature of 60° to 65°, and 70° to 75° by day; free ventilation will enable the fruit to swell freely, and develop good flavoured specimens, allowing a rise of 10° to 15° from sun heat. Keep water from the fruit, but the floors and other available surfaces should be damped, so as to afford a certain amount of atmospheric moisture for the benefit of the foliage. Water at the roots must be given both to the inside and outside borders, and a light mulching of rather short, lumpy material will lessen the necessity for it, and encourage surface roots.

Trees Swelling the Fruit.—In houses that were started in March, or where the fruit is taking the last swelling after stoning, syringe vigorously to keep down red spider. If the trees need support, supply liquid manure or water through a good mulching of short manure, sprinkling a handful of some approved fertiliser to a square yard before watering. Admit air early and in plenty with rising temperature, and insure the fruit swelling to a large size; close early with abundance of atmospheric moisture, allowing the heat to rise to 85° to 90° or more afterwards. Turn the fruit with its apex to the light, and draw the leaves aside or shorten them, so as to admit light and air to the fruit, and thereby secure its even ripening. Keep the shoots well but not too closely tied down, pinch the laterals back to the lowest leaf, thinning out the growths where crowded, and remove superfluous shoots.

Gathering Peaches.—Great care is necessary in removing the fruit. The least pressure makes a mark and spoils its appearance. A piece of wadding should be held in the hand and the fruit removed by gentle pressure, then laid carefully in a padded shallow basket. The fruit intended for packing should be gathered before it is dead ripe. Morning is the best time to gather the fruit, and it should be placed in a cool room to mature before being sent to table. In bright weather the trees should be looked over in the evening as well as morning for the removal of the ripe fruit.

Late Houses.—The fruit should be thinned to the quantity required for the crop, or a few more may be left than will be required, to allow for casualties in stoning. Syringe morning and evening in fine weather, but avoid syringing on dull days and on mornings when moisture has been condensed and hangs on the margins of vigorous trees in the early morning. Admit air early and freely. Mulch inside and outside borders with short manure, and supply water abundantly. Shoots not required for next year's crop, and those not needed for furnishing the trees, should be removed. Keep laterals closely pinched, and cut away gross shoots. The shoots on young trees should be left about 15 inches apart for next year's bearing, and if they are disposed to elongate above 18 inches they may be pinched to 12 or 15 inches; stopping the laterals at the first leaf, but extensions or main shoots should be allowed to grow their full length, provided they are evenly balanced and there is room. Avoid laying-in the growths too thickly; the branches should be 9 to 12 inches apart, and these should be as evenly balanced as possible.

Vines.—In Pots.—Stop the canes when from 6 to 8 feet long, pinching the laterals and sub-laterals at one joint as produced. This applies to Vines intended for fruiting next season. Those intended for planting may be allowed to make all the growth, and be cut back to two or three eyes or the length required at planting time, or when leafless.

Vines Cleared of their Crops.—Syringe occasionally to keep the foliage clean, afford water to render the soil moist. A mulching of short manure will prevent the soil cracking, and the moist surface will keep the roots from going down. Allow a moderate extension of the laterals, and admit air freely above 60°. There is no fear of the wood not ripening, and the difficulty will be to prevent the premature ripening and fall of the foliage.

Houses of Ripe Grapes.—These will be the better for slight shade from powerful sun. Some pilchard or double thickness of herring nets drawn over the roof-lights will mostly be sufficient shade, and a good spread of foliage will assist Black Hamburgs in keeping their colour. Moderate air moisture will not injure the Grapes if accompanied by free ventilation. Keep laterals fairly under, but a little extension will assist in the retention of the principal leaves, and upon their continuance in health depends the maturity of the buds for next year's crop.

Grapes Ripening.—When the Grapes begin to change colour admit a little air constantly, with sufficient heat in the pipes to maintain a night temperature

of 65°, 70° to 75° by day, with 80° to 85° or 90° through the day from sun heat. Avoid an arid atmosphere, damping occasionally, and do not allow the border to become dry. Vines ripening heavy crops will be assisted in perfecting them and storing food for the future by an occasional application of liquid manure. A light mulching of dry spent material will assist the Vines by securing uniform moisture, and thus keeping the roots near the surface, whilst avoiding excess of moisture, and thus preventing cracking. It is a confined and stagnant atmosphere that does most of the mischief in Grapes cracking and spotting.

Late Grapes.—Thinning.—Thin well to secure large and highly finished berries; such varieties as Gros Colman and Gros Guillaume about an inch apart, the oval-berried varieties not requiring as much room as the round ones, but all should be so thinned that they will have room for swelling fully without wedging, and yet be so close that when dished the bunches will retain their form. Loose bunches that show the footstalks are not so pleasing, however fine the berries, as those more compact. Shy setting varieties are often thin of berries through the number of stoneless ones that must be removed, to guard against which no pains should be spared in getting the wood ripe and in fertilising the bunches when in flower with Black Hamburgs. A pound of Grapes per foot run of rod is usually as many as Vines ordinarily finish well, therefore reduce the bunches so as to give about that weight.

Regulating the Growths.—Avoid large reductions of foliage at a time, it only tends to induce shanking through the check given to the roots. Keep the growths tied down from the glass, and so prevent scorching. Allow as much lateral extension as can have exposure to light, but the foliage should be rather thinner in the case of white Grapes than in black; this more particularly applies to Muscats. Always take care that the laterals do not encroach on the principal leaves.

Temperature and Ventilation.—Maintain a night temperature of 65°, and 70° to 75° by day in dull weather. Admit air early, providing a little at the top of the house constantly, increasing the ventilation with the temperature, allowing an advance to 85° or 90°, at which keep through the day from sun heat, reducing the ventilation with the declining sun. Close at 85°, damping the paths well then, and again before nightfall. Avoid cold currents or sudden depressions of temperature, as they cause rust and favour the spread of mildew.

THE BEE-KEEPER.

EARLY SWARMS.

"BEE Notes from Devon" (page 492) are interesting to bee-keepers in the midland and northern counties as showing the forwardness of bees, as well as vegetation, for which that delightful county is noted. At the date bees were swarming there they were clustered in their hives in South Yorkshire owing to the cold weather and high winds that prevailed at that time. "A. G." is to be congratulated on the forward condition of his bees, and for the promise of a glorious harvest from the fruit trees and white Clover.

"S. T., Gloucestershire," writing on June 5th, says, "On May 22nd I found the bees from one of my hives hanging out in a cluster at the entrance; I at once supered them. In spite of that they swarmed yesterday, and to-day I took off fourteen well-finished sections. I left in the others that were not quite sealed over, and filled the crate with empty sections. Bees are now doing well; 80° in the shade to-day." Had the above stock been supplied with another crate of sections a week after the first one was placed on the hive, as advised in previous notes, they would probably not have swarmed, but have continued storing honey during the spell of hot weather, attention being also given to shade and ventilation.

The first swarm in this district came off at 6.30 on the morning of 22nd May, and flew nearly a mile away, and was clustered before seven o'clock. It is not often bees swarm so early in the morning, but the old stock being in a straw skep, in a warm spot where the sun shone directly on the hive, caused them to leave. It is not usual for first swarms to fly so far before alighting.

The above were hived into a straw skep of medium size, and allowed to remain where they alighted. Ten days afterwards I examined them, and found the skep full of beautiful white combs, and crowded with bees; these were placed in a frame hive, and the skep placed on the top as a super, and as the bees are hatched the cells will be filled with honey, which will be in good condition owing to the newness of the combs.

As the above mentioned swarm was so much in advance of others in the district, I inquired the history of the original stock, and found they were in a straw skep, which did not swarm last season, neither was there any honey taken from it, and being in a warm dry place and wintered on natural stores was doubtless the cause of them being extra strong in bees this spring.

SWARMING *versus* NON-SWARMING.

This is a much-debated question. Under the old-fashioned system of keeping bees in straw skeps swarming was universal, and bee-keepers, in speaking of their success or failure, usually spoke of the number of swarms they had; and as a rule, the earlier the swarms were obtained, if the season proved favourable, the greater the surplus stored. If the chief honey harvest is obtained from the Heather, there would be no harm in allowing the bees to swarm, even under the modern system.

It could, however, be done artificially, instead of leaving it to chance. But where the honey harvest is obtained from early spring flowers, and finishes with the White Clover and Limes, and no second harvest from the Heather, I cannot see the advantage of the swarming system, as all the energies of the bees are required in raising brood and storing sufficient for their daily requirements, so as to derive full benefit from the honey flow when it comes, as it lasts but a short time.

If extra room is provided when required in the frame hive, and a system of rearing young queens is carried out, the non-swarming system is preferable; but where bees are kept in straw skeps, and there are some cottagers who will keep them in no other, then the swarming system is advocated in preference to any other.—AN ENGLISH BEE-KEEPER.

TRANSFERRING STOCKS.

I HAVE an old stock of bees in a straw skep, which I wish to shift into a bar-frame hive. Could I do so now without much loss? and if so would driving be the best method to follow?—H. SHAPLEY.

[Allow the bees to swarm, and place the swarm in the frame hive, using guide comb or full sheets of foundation in the frames. The latter is preferable, as much valuable time is saved. The bees remaining in the straw skep will rear a young queen. These should be driven from the skep at the end of the season, and if only one stock is required remove the queen from the swarm and unite with the driven bees. The colony will then be headed by a young fertile queen.

If the bees show no sign of swarming drive them in the usual manner until the queen is seen to go up into empty skep. This is important, otherwise it will end in failure. The frame hive being in readiness, and the frames prepared as above, shake the bees and queen into the hive, and place a piece of excluder zinc on the top of frames on which the skep containing bees and brood should be placed.

The queen will thus be kept in the body of the hive, and will fill the combs with eggs, whilst the workers will attend to the hatching brood in the skep. Three weeks afterwards the brood will have all hatched in the skep, when the skep may be removed, and a crate of sections or shallow frames be given instead. The skep may be allowed to remain as a super, but the honey will not be in as good condition as when stored in sections.—AN ENGLISH BEE-KEEPER.]

TRADE CATALOGUE RECEIVED.

Ant. Roozen & Son, Overveen, Haarlem, Holland.—*Dutch and Cape Bulbs.*

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

English Asparagus (J. D., Sussex).—The wholesale prices of this delicious vegetable vary from day to day in Covent Garden, according to the supply and character of the produce. On the 15th inst. the best Middlesex "grass" ranged from 3s. 6d. to 4s. a bundle of not less than 105 heads, produce from some other districts selling from 1s. to 2s. The best of everything pays the best, and when this or any other vegetable "makes nothing," it is either because the samples are inferior or sent at the wrong time. First-class Asparagus seems to be always in demand.

Pyrus Aria Propagating (J. C.).—This is the name of your flowering shrub. It may be raised from seeds, which usually remain dormant until the second year; by layers, which should be made in autumn, and notched at a joint, securing with a peg so as to keep the tongue open; and for standards by budding or grafting on the Mountain Ash, at the height required.

Azalea mollis Hybrids (L. K.).—The list given below contains some of the best varieties yet raised. They produce very large trusses of flowers, in unique and beautiful shades of colour not easy to correctly describe. We should also advise you to obtain a few unnamed seedlings, as something good is invariably found among them. Charles Rogier, Edison, Esmeralda, Frederie de Mérode, Général Brialmont, Gloire de Belgique, Henry Conscience, M. Desbois, Mignon, Oswald de Kerchove, Prince Baldwin, and Souvenir de Louis Van Houtte.

Fadyenia prolifera (L. S. E.).—This curious little Fern requires the temperature of an ordinary exotic fernery, or the cool end of a moist stove. It succeeds in a compost of peat and sand, with abundant drainage, a wide shallow pan being best suited for it, as the long narrow fronds can then extend freely. When the young plants are produced at the point they will soon root in the soil, and may be either separated or allowed to remain, the latter being generally preferred, as they impart a peculiar appearance to the plant. It is usually found advisable to cover the plant with a bell-glass to preserve an equable temperature and moisture about it.

Cucumber Culture (Mancunian).—The culture of Cucumbers is dealt with from time to time under the heading of "Fruit Forcing." The following brief hints will, however, be of assistance to you:—Turfy loam, inclining to be heavy rather than light, chopped up roughly, and about a sixth part of sweet decayed manure mixed with it (not rank manure) will form a good rooting medium. If you can add a shovelful or two of crushed lime rubbish and wood ashes to a large barrowful of the compost do so, but they are not essential. A temperature of 65° at night, rising to 90° in the day with sun, also plenty of moisture in the air and the soil, will promote rapid growth. A dry atmosphere favours insects, and dry soil arrests growth. Unless the male flowers are very numerous and the fruiting flowers sparse you need not trouble yourself about the former. Secure sound healthy growth, with the leaves fully exposed to the light, and good crops of Cucumbers will follow.

Cephalotus follicularis (S. E. W.).—This pretty and interesting little plant is a native of Australia, where it was first discovered by Labillardière, who described and figured it; subsequently Mr. Robert Brown also found a specimen during his voyage with Captain Flinders. It was first cultivated in England about 1822, and is now by no means a rarity. The plant is remarkable in several ways, for it is the only species of the genus, and is considered sufficiently distinct to constitute a natural order (allied to the Polygonums), and we thus have the peculiarity of a family composed of one individual. In the leaves, too, we find another singular feature—some are flat and elliptical in form, while others are converted into extremely neat and pretty little pitchers or aseidia, somewhat resembling those of Nepenthes, only much smaller. They are dark green with a purplish shading, and pink veins, and are furnished with small lids, the mouth of the pitcher being bordered with a dark-coloured furrowed ring. This Cephalotus is an inhabitant of marshy land; it should therefore be provided with a soil composed of peat and live sphagnum moss, the pot being well drained and placed in a shallow pan containing water. If the plant is grown in a pan, that should be placed inside another larger one, the space being filled with fine Derbyshire spar and kept constantly moist. In either case a bell-glass should be placed over the plant. The best position and temperature is the cool end of the stove or Orchid house, where with careful attention in supplying the requisite moisture the plant will grow freely.

Holly Leaves Blistered (Subscriber to "our Journal" for nearly Twenty Years).—The Holly leaves are much disfigured by the irregular pale blotches on the upper surface, which gives them a blistered appearance. These are spaces mined in the green cellular tissue, and are the work of the larvæ of the Holly leaf fly (Phytomyza Illeis). Commonly, two or three larvæ are to be found in a leaf, each in its own mine. They are about one-tenth of an inch in length, yellowish-white, with a dark brown or black mouth. The small, oval, brown-ringed pupæ may be found in the mine in the winter, where they remain until the early summer, and then emerge in the perfected form. This is a two-winged fly, black, with pale yellow proboscis, except the black palpi and hairs. The most successful plan, next to destroying the insects by removing the mined leaves and burning them, which we do not advise, as it greatly weakens the trees (and must be done whilst the insects are in them, which they are not now), is to syringe the trees with a solution of soluble petroleum, which may be readily made by dissolving 1½ lb. of soft soap in a gallon of water by boiling, and when dissolved remove from the fire for safety, adding at once 2 gills (half a pint) of petroleum, stirring briskly till amalgamated, and dilute to 10 gallons for use by adding the required amount of hot water, but not using till cooled to 90° to 100°. It should be applied at the end of May or early in June as a preventive of attack. We have used it during attack with good results, as the petroleum seems to sink into the mined portion of the leaf, and destroys the pest in the mine.

Soil in Which to Sow Seeds (Tyro).—Exact proportions of loam, leaf soil, and sand cannot be given without knowing the nature of the loam. Obviously sandy loam does not need half the quantity of sand added that is requisite in strong or clayey loam, and similar remarks apply with reference to leaf soil. As a rule rather strong loam may have an equal quantity of sifted leaf soil added, and about a tenth part of sand, or more if the loam is sandless. Assuming seeds are good much more depends on the depth they are covered and uniformity of moisture than on any particular proportions of soil ingredients.

Plunging Greenhouse Plants (Novice).—Many greenhouse plants may be placed outside with advantage during the summer months, such as Camellias, Azaleas, Tea Roses, Callas, and Cytisuses after their growth is made. The pots require to be plunged, so that the roots which cluster round the sides of them may be kept in a cool moist condition; for when the pots are exposed to the full blaze of the summer sun the soil is rapidly dried, as well as heated, to an extent which causes destruction to the young active roots, to say nothing of the greater necessity for more frequent supplies of water. Plunging provides against all this, and should always be practised. The very best material to plunge the pots in is ashes. Plunging in garden earth is commonly practised; but it is not a good plan, for worms find their way into the pots, to the detriment of the roots and injury to the plants. Worms do not pass readily through ashes, and therefore these should be chosen for the purpose.

Propagating Scarlet Honeysuckle (E. C.).—All the "creeper" Honeysuckles, which, of course, include the Scarlet Honeysuckle (*Lonicera sempervirens*), are mostly grown from dormant cuttings—that is, the ripened growths of the current year are cut transversely below a bud or joint, and the cuttings, 6 to 8 inches in length, inserted in sandy soil two-thirds of their length, pressing it firmly about them, and watering to settle it. This is usually done under a hand-light or frame in a sheltered situation, the cuttings being inserted in the early autumn, generally at the end of September or early in October. Some take the cuttings with a heel—a small portion of the preceding year's wood—selecting stubby growths. The cuttings will callus during the winter, and start into growth in the spring, when they may be lifted carefully and potted singly, or left until the following autumn. Layers are also had recourse to, which is a sure method. The layering should be done in the autumn, making choice of firm young wood and placing at least one joint in the soil about a couple of inches deep. This may be done in a plunged pot, and the following autumn the layer will be well rooted, detached from the parent.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Dianthus*).—1, *Salisburia adiantifolia*; 2, *Abies orientalis*; 3, *Abies Tsuga*; 4, *Taxodium sempervirens*. (*H. D.*).—1, *Cercis siliquastrum*; 2, *Ercilla spicata*; 3, *Lilium pyrenaicum*.

NOW AND THEN, OR 'TIS SIXTY YEARS AGO.

EARLY in this century a new writer arose—a writer who veiled his identity for a long time—a writer who brought all the reading world to his feet. His first work was entitled, "Waverley, or 'tis Sixty Years Ago," and it was not until he had published several other volumes that he became revealed as Sir Walter Scott. The events he depicted were full of life and go—battle, rebellion, and murder. But what were all the years of his life compared with these last sixty years during which her gracious Majesty has held the sway over us?

In many cases changes come so gradually; the transition from old to new is so slow that we are not fully aware of their magnitude. It is only when we come to some great or notable turning point or milestone, and look back on the way we have travelled, that we at all estimate the distance we have covered. We rest and spend some little time in retrospect, and move on sadder and wiser.

This year of a glorious anniversary is a stopping place to pause and reflect. The Royal Agricultural Society is one year younger than her Majesty's reign, and if arts and sciences have taken giant strides so has agriculture. There are three classes of society intimately interested in this great industry—landlords, tenants, and labourers—and their positions are about reversed. In 1837, and for some decades after, landed property was held to be the best of investments. Now it is considered one of the worst. There was a day of prosperity for landlord and tenant in the sixties, to be followed only by a night of prolonged darkness. The labourer did not earn, in the southern and eastern counties, enough to keep body and soul together; now, for shorter hours, he gets liberal payment.

All the burdens on land have increased a hundredfold, and there are no compensating clauses. Perhaps machinery is the thing in which we see the most marked improvement. It is hardly possible to find any implement of husbandry as it was sixty years ago; our children do not understand what a flail can be, and except for Bible reference a sickle or reaping hook are dead letters. Take the simple plough of our forefathers, put it side by side with the varieties introduced by a hundred makers.

Think of the time when one drill was the boast of a parish, and an old Crosskill reaper the wonder of a neighbourhood. All manner of steam appliances that are now used, and used so unconcernedly, are the result of hard brain work, and we make of steam our handiest servant. Who does not remember the hordes of hard-working Irish labourers who came year by year to harvest our heaviest crops, and who could work—yes, and drink and fight too—as no Englishman could? They are in the vanished past.

Had this been written thirty years ago we should have spoken of land reclaimed from common and moor and brought into cultivation. Now as a set-off we sorrowfully turn to parish after parish of derelict land, hanging like a dead weight on the neck of the poor owner. There used to be the joy of harvest, a bountiful harvest, a blessing to all. Now we gather in our limited crops with little pleasure, knowing that our best efforts are swamped by the myriad bushels poured into our seaports by the intelligent foreigner, who has found out how to produce the "staff of life" more cheaply than we.

There is one thing to be said in favour of this invasion. We remember as children, after a wet harvest, the dark, dank bread we had to eat. Now this is all changed. The cottager has white bread on his table fit for a palace, and at a much lower cost than the bread of the past. John Bull likes to brag a bit, and when he can honestly do so let him have his fling. We can grow the best pedigree animals the world ever saw. We breed with care, with skill, and we spare no money. Our temperate climate and green meadows have much to answer for; but where would they have been without our enterprising race of tenant farmers, the backbone of the stock breeders? We do not think lightly of the help rendered by the upper classes, but we feel that the steady pluck and personal superintendence of the intelligent farmer has been the source of all our success as stock raisers. We raise for all the world.

Some classes have gone down; take coach horses, for instance. The roads are better now; a lighter class of horse is needed, something smarter, and the coach horse proper is a thing of the past. Take, too, the modern hunter; he is quite of a different type from the short-tailed, stiff animal portrayed in old pictures. Where is the Durham ox? Merged in the magnificent Shorthorn.

We breed now for early maturity; we breed to have no coarse cuts and no fat greasy mutton. A departure of modern days has been the Shire horse. Draught horses there were in plenty, and some of them of an excellent type, but it has been the work of the last twenty years to develop and classify in stud books the sires and dams whose pedigrees are as long and whose value is almost as great as Derby winners. The last ten years has seen a most marvellous development in this one branch of agricultural industry. The modern hackney, too, is an innovation—pedigree and action first and last, and a fancy price to boot.

Then what about all these shows at "Merrie Islington"—Shire Horse, Hackney, Hunters, Improvement, Dairy Show, and Fat Stock? The Dairy Show is, if we may use the term, a grand invention, and has given a marvellous impetus to milk producers, dairy workers, and dairy appliance makers. Reflections have been cast upon our dairy work; we are told how vastly superior is the foreigner, and yet no foreign nation can get up such a show as we have annually in October. We cannot touch in this paper on the noble work done by the "Royal," nor can we refer to those talented men who make that society what it is by their strenuous, unceasing efforts.

There has been a tremendous advance in science as applied to agriculture, but it is folly for us to think that science can possibly take the place of the patient, practical observation of a lifetime. Farming cannot be learned from a book, but the book read by the light of experience increases the knowledge twofold.

WORK ON THE HOME FARM.

We have had a few fine days with great heat, then a change to (Wednesday) wet and cold. Swedes are about all in, only a few rows remaining to be drilled; they have gone in well, except in one or two strong places, where there is always more or less difficulty.

The early sown Mangolds are a full strong plant, and are looking grand and nearly ready for striking out; the later sown did not all come from the drilling, the soil in places being too dry; they are all coming now, but will be late. They may soon make up lost ground if the season be a hot one; in the meantime, the others have got a good start, showing the value of early seeding—the early bird again.

All kinds of vegetation have made enormous progress since our last. Wheat will soon be shooting; Barley and Oats are more backward, but doing well, especially the latter. Potatoes are coming to the hoe too fast to be attended to as soon as they should be. Indeed, now the corn is looked over and Swedes are sown Potato weeding and earthing are

the operations most pressing on the attention. Mangolds and Swedes will require hoeing very shortly, so there is no time to lose.

This rain and cooler weather will again postpone the cutting of Clover for hay. As long as the lower leaves are not dying and dropping off the crop must be gaining in weight. It is impossible to get every flower into bloom without losing leaf, but Clover should be in full bloom before cutting. Cowgrass requires cutting earlier than Red Clover, as it is very coarse and strawy if allowed to stand too long.

The cool wet weather may cause trouble amongst the ewes lying on the cold wet ground, being liable to cause downfall in the udder. This complaint requires early attention, being very dangerous if neglected. The animal should be put in a dry pen or shed, fed on a little weak gruel and hay, first having a drench of 2 ozs. of Epsom salts and 1 oz. of ginger given in gruel. The udder should be gently rubbed with goose grease on the hard portions. The drench may be repeated as the effect appears to have worn off, say the second or third day. A dry layer is very essential, and no access to water.

CHICKENS FROM EGGS (EIGHTEEN MONTHS OLD).

It may interest many of your agricultural and suburban readers to know that a novel method has been discovered for preserving eggs perfectly fresh for twelve months or more, not only for eating, but for hatching purposes. It may appear incredible to many poultry keepers that the germ of an egg can be kept alive for so long a period, for under ordinary circumstances it is well known that eggs become more or less stale for eating, and will seldom hatch chickens if more than three weeks old.

The new method is as follows:—Wrap each egg the day it is laid in a small square of newspaper, and pack these eggs side by side in a box, layer upon layer until it is full. After the lid is fastened down it must firstly be stored in a dry cool place, and secondly, be turned upside down at least three or four times a week. This simple process of turning will preserve eggs perfectly fresh for twelve or even eighteen months.

A neighbour of mine has for several years hatched out a lot of chickens from eggs so stored and turned twelve, fifteen, and some eighteen months after being placed in the box. As 1000 eggs can be stored in a single box, and turned in a few seconds, it is clearly to the advantage of housekeepers to "box" eggs in the spring when they are eighteen for 1s., and consume them at Christmas when they are six or eight for 1s.—KINARD BAGHOT DE-LA-BERE, *Burbage Hall, Leicestershire*.

[The method which our correspondent describes is subdivided into (1) wrapping in newspaper, and (2) turning frequently. Enveloping eggs in newspaper is not by any means a new method of preservation. We have before heard of and adopted this plan in preserving eggs for eating purposes. The newspaper, in that it excludes the passage of air through the porous shell, retards decomposition and destruction of the germ. Similarly ice is prevented from melting rapidly in hot weather by being well wrapped in newspapers. Another proof of the non-conduction of heat by paper is the fact that if a newspaper be sandwiched between two blankets on a cold night radiation of heat will be much retarded, and the sleeper kept much warmer. Such methods for the preservation of eggs as greasing with butter or immersing in a solution of lime illustrate the same principle of excluding air, but unfortunately eggs thus preserved are of no use for hatching purposes, since the chicks in order to hatch alive must have a supply of oxygen, which is impossible if the pores of the shell are choked with grease or lime. We think, however, that our correspondent attaches undue importance to constant turning, for movement is likely to damage the vitality of the germinal spot, and believe that if the turning of the eggs were omitted quite as good, if not better, results would ensue, provided the eggs were carefully wrapped in paper as soon as possible after being laid.]

6th.—Sunny morning, but hazy and close; slight showers in afternoon and evening, with a little distant thunder.

7th.—Overcast almost throughout, and spots of rain in evening.

8th.—Overcast and drizzly, with rain from 11 A.M. to 1 P.M. and after 11.30 P.M.

9th.—Continuous rain from 0 A.M. to noon; dull, drizzly, and showery after.

10th.—Overcast at times, but generally fair and some sunshine.

11th.—Sunny morning; much thin cloud in afternoon.

12th.—Bright and warm throughout.

A variable week, but mean temperature near the average.—G. J. SYMONS.

ROYAL DIAMOND JUBILEE.

1837.

1897.

IN HONOUR
OF
THE QUEEN.

JOURNAL OF

HORTICULTURE.

WHEN her Majesty the Queen had occupied the Throne for the remarkable period of fifty years great were the rejoicings among the millions of her loyal subjects. On that auspicious occasion no section of the inhabitants of the kingdom was more anxious to do honour to the event than that which is composed of horticulturists. Many there are who still remember the great devotion of the late Prince Consort—a patron of all that was good—to the art of gardening, and how effectively he was assisted and encouraged by his Royal help-meet, who is still happily our gracious Queen.

It is not too much to say that when the great leader in gardening—for such he was—was called away the whole heart of the nation went out to the Royal mourners. The Throne and the People were felt to be very near together then; and there has been no separation. The same deep-seated love and loyalty remain, but strengthened by time, and the fact asserts itself in a manner which cannot be mistaken on the occasion of any event that marks an epoch in the nation's life.

When such events are of a nature to evoke feelings of thankfulness and joy these find spontaneous expression, not in words alone, but worthy acts. This was so in 1887, and now we have history repeating itself in 1897, but in still more emphatic form. The event is greater, rarer, unparalleled, and hence unique. Sixty years a Queen! and such a Queen! surely the kindest and

the best, and certainly the ruler of the greatest monarchy in the whole wide world.

What wonder that her subjects should rejoice; that they should gather together from the ends of the earth—swarthy sons of the empire from Africa and Asia, hardy and enterprising subjects from North America and far-distant Australasia? At home all classes and creeds, representative of all arts and crafts and sciences, each and all in their own way doing honour to the great occasion and homage to the head of all—their noble Queen. Scattered as may be the dominions under her sway, the spirit of unity breaks through the bonds of distance, and races are drawn together under the magnetic force of a great personality—the embodiment of freedom and justice, with all the attributes that have made the British Empire what it is to-day—stronger, richer, and better than it has ever been before in all the annals of its long and stirring history.

Returning to our immediate domain, two incidents may be first noted which are known to be in precise accordance with her Majesty's aspirations—namely, that where practicable the rejoicings of the present year shall be in the form of strengthening public charities, or relieving distress. We have a noble charity in the gardening world that has done truly noble work during almost the whole period of her Majesty's marvellous reign, and of which the Queen has been Patroness for forty-five years. This is the Gardeners' Royal Benevolent Institution. Since its establishment

fifty-nine years ago this grand charity has distributed £71,000 to worn-out gardeners, horticulturists, and their widows, and has now on its funds men and women who are receiving permanent relief at the annual cost of nearly £3000. This is a great achievement, though the claims on the exchequer are unequal to meet the ever-pressing demands of gardeners who are no longer able to labour, and whose small savings are exhausted. This Institution is seeking (and happily with good promise of success) to commemorate her Majesty's glorious reign by raising a special fund, to be called the "Victorian Era Fund," for the benefit of applicants who are awaiting aid which cannot at once be granted through lack of means.

We have also a younger charity that links in a manner most gratifying the rejoicings of 1887 with those of 1897 among the gardening community. The year first named will always be memorable, as it was in celebration of the great Royal event which then occurred that the Gardeners' Royal Orphan Fund was established, with the object of affording help for helpless children born into the gardening world, and hope for the widows who were almost crushed down with despair. The need for such a charity was evident by the pressing applications for aid, and year by year candidates had to grieve under the bitter disappointment of failing to secure election to its benefits; but—and here comes the golden link in the chain which connects the two great years of rejoicing—the charity, inaugurated in 1887, is in 1897 supporting seventy children at a cost of nearly £1000 a year, with a reserve of £10,000. This is a splendid result to have been accomplished in the time; but it is not all. Desiring to commemorate this greater Jubilee of our good and gracious Queen, those who are responsible for the conduct of the Fund felt that in no way could they carry out their desire so fittingly as by dispensing with an election altogether, and placing the whole of the candidates on the benefits of the Institution.

Those endeavours to celebrate, on the lines suggested, an event which has no parallel in the annals of history afford conclusive evidence of the deeply rooted loyalty that is established in the horticultural community, while the form of its manifestation is such as must command the widest possible approval. There are other forms, however, of celebrating the unequalled reign during the present memorable year.

The Royal Horticultural Society, as befits its high position, provides a new medal different from all others existing—the "Victoria Medal of Honour in Horticulture"—as a distinction to persons who have rendered good service in some of the various branches of the art—as scientists, cultivators, raisers of new products, discoverers, or writers. This may be regarded as a permanent memento of the sixty years' reign, and there can be no more than sixty Victorian medallists at any one time—a happy idea, and the honour of the distinction will be cherished by its possessors.

In addition to this, the Society, desirous of assisting in bringing together the most extensive and varied display of the products of British gardens, where such display can be witnessed by the greatest number of persons who usually assemble on such occasions, its patronage is to be given to the greatest provincial horticultural society in the kingdom. This is the Shrewsbury Society, and it may be confidently expected that no such representative example of British horticulture, in its ornamental and useful aspects, could be provided elsewhere as in the town to which many thousands wend their way on the occasion of the great show and gala in August. This year the exhibition is to be distinctly commemorative of the Diamond Jubilee. Thus, while the Royal Horticultural Society gives all the encouragement within its province to the charitable institutions, it is doing its duty in other directions during the present eventful year in honour of the Queen.

We have said that her Majesty, and the much and long-mourned Prince Consort, were, in days long past, great patrons of horticul-

ture. Some gardeners and garden lovers still remain who, with ourselves, can remember the famous shows at Chiswick, when the gardens were thrice the extent they are now, and the brilliant assemblages on those occasions. They will call to mind the Queen and Prince Albert, with the then young Royal Family, all blithe and happy, examining and admiring the products, while the exhibitors had the privilege of standing near their collections. As we are reminded by a septuagenarian gardener, 4000 carriages have been known to drive to Chiswick on a show day. How many hundreds, he asks, would do so now? Well, times have changed, and the gardens have changed. Shows of garden produce were comparatively few and far between then, whereas they are now to be seen almost everywhere. They are no longer novelties, but would almost seem to have become necessities of life, and more will be provided this year, to be attended by an infinitely greater number of persons in the aggregate than ever assembled on such occasions in the "palmy" days of the long ago.

But we are dealing with the question of Royal Patronage in horticulture. We do not know for how many years the Queen-Empress has been patron of the Royal Horticultural Society, but we know that the Prince Consort was elected President in 1858, and this is what was said in the *Journal of Horticulture* at the time:—"The Society will congratulate itself on the appointment. The Prince is a popular man, fond of improvements in all branches of natural science; but after all the great source of his popularity is his natural kindness and affability—two of the strongest qualities under Heaven for uniting the most opposite minds into one compact body." We also know that all the Royal Princes and Princesses were elected Fellows on January 31st, 1860. The South Kensington scheme had then started, towards which the Queen subscribed £1000, and the Prince Consort £500. The gardens once famous, but long since blotted out by the inexorable force of events, were opened by the gardener Prince in 1861, who closed his speech on the occasion with the following heartfelt hopes:—"May your efforts meet with public approbation. May that approbation give you all the support required to carry out on a larger scale than heretofore the useful objects for which you are incorporated."

The Royal President perceived, as if by intuition, that if the Society were to flourish it must be—like the Throne itself—"broad based upon a people's will," the will and desire of horticulturists. From that will there was, mainly in consequence of the great lost leader, a sad departure, but fortunately a return to legitimate objects brought about the great revival, which never since the historic change was so marked as at the present time. This is the effect of wise government—a Council of the Society as loyal to horticulture in its broadest aspects as to the person and throne of its Imperial patron, our noble Queen.

Two other events cannot be forgotten in which her Majesty took a prominent part, and which gave considerable impetus to the progress of horticulture—namely, the opening of the Great Exhibition in Hyde Park in 1851, and of the Crystal Palace at Sydenham in 1854.

Of the great Hyde Park Exhibition it was said at the time in our columns:—"Mr. Paxton's beautiful structure bids fair to set people thinking about the best methods of erecting plant houses in the future. Instead of leaning them against walls for support, we shall find it possible to make them stand on their own legs, and be as cheaply heated and be far better, not only for plants, but Grapes and Peaches as well; and then we shall learn more of pleasure ground gardening through the influence of this exhibition during the next few years than we have learned from all the books and shows of the past." The prophecy of the glass structures has been exactly fulfilled, while few will deny that the transportation of the "Palace of Light" to Sydenham, with all the resulting accessories, exerted a great and lasting influence for good in the diffusion of the taste in gardening throughout the community.

By kind permission of Messrs. W. & D. Downey,
57, Ebury Street, London, S.W.

Relative to the opening of the Crystal Palace where it now stands, we find the following allusions in our issue of June 22nd, 1854, and which may be appropriately cited:—"The spectacle was not to be forgotten. On the central platform stood a Royal Family, unequalled by any of its contemporaries, whether as an illustration of English domestic happiness, or as an example of a monarch wisely careful to promote the home improvements and pleasures of her subjects. Three generations were in the Royal group, and no one could look upon it without the conviction that husband and wife, child and parent, were examples of reciprocal affection. It spoke out in every action—from the Queen's mother placing the shawl over the Queen's shoulders, down to the whispers between the young Princes and their father; but let us not, in the admiration of our Sovereign, forget the great object in view—namely, fostering the good taste and good habits of the least wealthy classes." This is what the Queen has always sought to do, and much has been accomplished through the agency of the pure, wholesome, intellectual art of gardening.

Recognising the intimate connection of her Majesty with horticulture over a much longer period than the majority of those who are identified with the ancient art, the *Journal of Horticulture*, whose jubilee is also near, and as reflecting the desire of its widely scattered constituents in the British Isles and distant Colonies, desires to share in the celebrations of the present time in a manner not inappropriate, and in accordance with the precedent of ten years ago. In the carrying out of the project on a more extended scale than on that occasion, it will be seen what has been done and is being practised in the gardens of the Queen; and in order that the narration might more nearly approach completeness than heretofore, permission was sought for the requisite facilities, also Royal sanction solicited for the publication of a portrait of her Majesty. The following letter from Lord Edward Pelham Clinton, K.C.B., will show how readily our requests were complied with:—

WINDSOR CASTLE, FEBRUARY 27TH, 1897.

TO THE EDITOR *Journal of Horticulture*.

SIR,—In reply to your letter of the 17th inst. I have pleasure in informing you that the Queen has graciously granted the request contained therein.

With regard to the Royal Gardens here, including the Slopes, Frogmore Gardens and Adelaide Cottage, Mr. Thomas, who has already been informed of the wishes expressed in your letter, will afford you every facility for illustration and description.

I have no doubt you will receive every assistance for the same purpose at Buckingham Palace, Balmoral, Osborne, and Hampton Court by producing this letter; but should you find any difficulty I shall be very glad to send an order of admission to the different places.

I beg to remain, Sir,

Very faithfully yours,

EDWARD PELHAM CLINTON.

Our first desire is to express publicly our grateful appreciation of the privilege so graciously accorded by her Majesty, and promptly transmitted by the Master of the Household.

In appropriate connection with the descriptions indicated it is proposed to associate a general survey of horticulture during the last sixty years. This will in no sense be a formal chronological record of events obtained by literary research; but rather a series of personal reminiscences, fresh from the fountain of memory, by probably the only person living who could have provided them in the same interesting and entertaining way—the Rev. H. H. D'Ombra, to whom we tender at once our congratulations and obligations.

The present issue of the *Journal of Horticulture* will thus be commemorative of a great historic event—an issue such as its readers will be glad to possess, together with reminders of changes and occurrences in gardening during the period which it covers; while it is hoped useful lessons will be embodied as derived from practice in the Royal Gardens, which has proved so satisfactory in the various departments. Attractiveness is of necessity the main feature of several of the Royal Establishments, but in the chief

of them utility is also present in its severest form, the value of the work being tested by exact records, comparison, and results. Before, however, describing modern practice, concise reference may be made to ancient history, and some contrasts with the present will not be overlooked.

Windsor Castle Gardens in the Past.

FROM the scanty information which can be gleaned from "Tighe and Davis' Annals of Windsor" it may safely be affirmed that gardens of some sort have existed at this ancient fortress almost from the time of the Norman conquest. We are fortified in this affirmation by the first historical mention we have of a garden at Windsor Castle, where it is stated that King Henry III. gave the Constable of the Castle instructions that the Church should have tithes of the Royal Gardens, Windsor. This was in the year 1231. The garden must have been in existence long before this, or it would not have been in a position to pay tithe to the Church out of produce grown and sold; and in the absence of evidence to the contrary it may fairly be said that the Royal Gardens have paid tithe to the Church regularly from that long time until the present day.

Henry III. seems to have been more or less a gardener king, for again we find him giving instructions that a garden for himself and Queen Mary be included in some additions made by him to the Castle, and, furthermore, he commands that the house of the gardener and the hedge about the garden are to be repaired, as well as a certain plantation formed. Later on the King's projects for carrying out improvements to the Castle were for the time stopped by financial difficulties, but not so his ardour for improving his garden; for we find that, in face of these difficulties, the King gives instructions that a fountain of freestone is to be constructed in the garden, and he also, at the same time, commands the "custos" of Cookham and Bray to turf the herbarium, to complete the drains, and to make a well in the garden.

After the death of Henry we find no further mention of a garden at the Castle until Edward III.'s time—1327—when we come across the King's instructions to the Constable to pay John, the gardener of the King's garden without the Castle, twopence halfpenny per day! Instructions were also given, at the same time, that the houses and walls of the King's garden were to be repaired. We may wonder what sort of houses they were in those days. Among the relief provided by the King at this time to his soldier knights—who, in their old age, had fallen on bad times and decay—was a garden. What a happy thought! Where on earth are greater pleasure and consolation found?

Nearly a hundred years have flown before we again come across any mention of a garden here. This time it is associated with the name and memory of King James of Scotland, who was here detained a prisoner by Henry V. It was here, and at this time, that the Scottish King saw from his prison window Joanna, the beautiful daughter of the Earl of Somerset, walking in the garden; with her he fell in love, and they were subsequently married. It was here King James composed his beautiful and pathetic poem—"The King's Quail."

In 1483 King Edward IV. entertained at great festivities and rejoicing the Governor of Holland under the Duke of Burgundy, who had hospitably rescued him from pirates when the king had been forced to leave England for a time to take refuge with his brother-in-law, the above-mentioned Duke, and one of the last items on the programme was the King showing him his garden and vineyard of pleasure.

Little more is said of the Garden until the time of Queen Elizabeth (1603), when it is mentioned that a plan had been drawn for a new garden, at an estimated cost of £418 14s. 8d., including the walks and planting, and the gardener's wages at this time were stated to amount to the munificent sum of £4 per annum. The next news we hear of the Royal Garden is in the time of James I., when it seems it had fallen on bad times, as it was given or leased to the Corporation of Windsor for ninety-nine years, and afterwards for another term of forty-one years.

In Queen Anne's reign greater attention and encouragement seems to have been given to gardening, especially the planting of trees. It is here stated that a considerable sum was expended in that year (about 1705), by Henry Wise and Michael Strudholme, the former the Superintendent of the Garden, the latter having charge of the construction of roads

and other works in the Park. At this time an estimate was prepared for making a new garden on the north side of the Castle at a cost of £6874 18s., for the purpose, so tradition says, of commemorating the glorious battle of Blenheim. This work was never completed, although it was so far advanced that its outlines may still be traced on the turf of that portion of the Home Park where it existed. It may be mentioned here that this land is occasionally subject to floods, and this may account for the project being abandoned.

ANCIENT VINEYARDS OF WINDSOR CASTLE.

That Vine-growing for the purpose of making wine was practised to a considerable extent in many parts of the South of England in olden times is beyond dispute, as abundant records prove. The historical battle of Hastings was fought near a large plantation of Vines. Domesday Book, a statistical survey of England, prepared by command of William the Conqueror during the latter part of his reign (1066—1087), contains thirty-eight entries of vineyards then esteemed

ponderous round tower of the Castle stands. This is now a delightful old-world garden, containing venerable fruit and other trees, as well as herbs and hardy flowers, though on one side there are modern flowers in a scroll bed.

It is said that vineyards became gradually neglected in England after the acquirement by conquest of a portion of the wine-producing districts of France. The battle of Poitiers (1356) was fought in a French vineyard, consequently it is said French wine became the fashion—relished as the produce of British possessions in France; but wine was long subsequently produced in England, and there is little doubt that by growing a wise selection of Vines in the most favoured positions, better wine could be obtained from home-grown Grapes than is found in some of the Continental concoctions. It is to be presumed that the varieties of Grapes which used to be grown in the ancient Windsor and other vineyards are no longer to be found in this country, except, perhaps, in the Marquess of Bute's collection, obtained from the North of France.

FIG. 104.—WINDSOR CASTLE.

valuable. Down to the latter part of the seventeenth century vineyards were scattered over many parts of the South of England, and extended as far north as Peterborough. The Bishop of Rochester sent King Edward II. both Vines and Grapes of his own growth, perhaps for comparison with the produce of the Windsor vineyards. Be this as it may, there is no doubt that Grape-growing in the open air for wine making was an important item of work at Windsor Castle in the olden time, as we find about the year 1300 that among the many appendages to the Castle at this time was the vineyard. The pay of the vintiger and the expenses of gathering the Grapes are among the regular annual charges relating to Windsor on the pipe rolls.

Lambard says that "it moreover appeareth that tithe hath been paid of wine pressed out of Grapes that grew in the little park there to the Abbot of Waltham, who was parson both of Old and New Windsor, and that accounts have been made of planting the Vines that grew in the said park, as also of making the wines, whereof some parts were spent in the household and some sold for the King's profit." The Chaplain of the King's Chapel at this time (1272) received 30s., and the Keeper of the Vineyard the same—for how long a service is not stated. As late as the time of George III. a small vineyard existed on the ground outside the south wall of the lower ward of the Castle, and between it and Castle Hill, east of Henry VIII. Gateway, a spot now covered with a beautiful lawn. It is reasonable to expect, too, that Vines were grown on the steep sides of the great mound on which the

The Gardens and Pleasure Grounds of the Queen.

FROM the time of George III. to the accession of her Majesty to the Throne very little matter of interest is recorded in reference to gardening at Windsor Castle; but with the advent of the Queen the darkness and mists of the past gradually vanished, and a new and brighter era for gardening was ushered in. The great supply gardens at Frogmore were formed, and from then till now continued progress has been marked in all departments; and it may be said that every aspect of gardening is appropriately and admirably represented in the Royal demesnes.

Ornamentally we have every feature, from wild forest scenery to semi-dressed woodland charms; placid park, with stately trees; broad drives, with clean smooth surfaces and lawny margins; noble avenues and charming vistas; glistening water, meandering between richly wooded slopes, and embracing picturesque islands; the smoothest of smooth lawns, encircled and intersected by splendid terrace walks; flowers, old and new—old as in the ancient Dutch garden, more modern as in the later styles of home adornment; plants of various kinds and for definite purposes, and in enormous numbers in the aggregate, with a bountiful supply of all other requisites which gardens afford, as contributing to the health and happiness of those who possess them. The

great supply gardens of Windsor will be subsequently referred to. At present we will take a survey of the beauties of Nature and Art which surround the great and good monarch's glorious home.

It may here be stated that what is commonly understood as the Royal Gardens, Windsor, includes in this enumeration the following departments:—The Castle terrace flower garden, the slopes and Adelaide Cottage garden, the drives and plantations in the Home Park, Frogmore House grounds and gardens, and the following gardens some distance from Windsor belonging to the Queen:—The Royal Lodge, in the Great Park; the great Vine at Cumberland Lodge, also in the Great Park; the Queen's garden at Virginia Water, and at Aldershot; also the private garden and the old Vine at Hampton Court Palace—all, as well as the great charge of the Royal kitchen gardens, Frogmore, under the supervision of her Majesty's head gardener. Endeavour will be made to note some of the most interesting portions of the Royal Gardens, so far as the *Journal of Horticulture* may contain a description of them.

THE CASTLE AND FLOWER GARDEN.

Firm as the rock on which it stands towers above all that is near the majestic Castle of Windsor. The splendid residence of a long line of monarchs, it typifies the solidity and strength of the nation, while in dignity and repose it seems to represent the ideal of calm security—not so much a fortress as a home. Massive and picturesque in its broad outline is the magnificent pile (fig. 104, page 547). Imposing is its magnitude; marvellous is its preservation. It seems to have passed unscathed through the centuries, and the absence of flaw anywhere to be seen suggests its power to pass through many more. To the historian it is as a book of infinite treasure, not only in the wealth of its unrivalled library, but to him the history of England is written on every stone. To the true Briton at home and abroad the old Castle is the embodiment of England's life, wealth, and power, and above all does it appeal to the hearts of the sons and daughters of the Empire as the Empire home of their much-loved Queen. Striking are the characteristics of Royal Windsor, and perhaps the most significant of these is the healthy atmosphere of freedom which is felt to surround it. Apart from encroachments on its privacy as a home, to which the humblest cottage in the land is entitled, its portals seem to be open to all; while on fitting occasions the charms of its surroundings—its noble terraces, its beautiful garden, the strains of joyous music that enliven, the flowers which smile, the freedom that inspires—all are alike shared at the same time by Sovereign, princes, and people, and the more enjoyed by all because of the happy association.

The Castle garden is reached by visitors either through the main entrance on the west, nearly opposite the Great Western Railway Station, or from the north, near the terminus of the South-Western Railway, by the portal and the route known as the "Hundred Steps," but actually as near two hundred, which zig-zag their way up the heavily wooded sides of the ponderous escarpment. Seats are thoughtfully provided at the top for those who need a moment's rest before traversing the famous North Terrace. From here the scene is without a parallel. Far overtopping the tallest trees we look over the battlements into the great umbrageous depths below.

Reaching the north-eastern corner of the Castle, the bright and beautiful garden comes into view—a garden different from any other in position, configuration, and adornment. It is a garden of art emphatically, yet not the art that chills; there is a well-balanced proportion of broad gravel walks, deep grassy slopes, wide sweeps of lawn, large beds of flowers, effectively associated with elegant Conifers and ornamental shrubs. From this terrace garden looking to the left a glorious view is obtained of the woods of the slopes, and skirted as they are with flowering trees in great variety, such as Lilacs, Thorns, Laburnums, and Weigelas in rich bloom, the sight is one not easily forgotten. From here is also obtained a panoramic glimpse of a part of England most interesting and beautiful. To the north-west is seen the Oxfordshire hills and the River Thames, as it quietly winds its way towards Windsor, and the far-famed Eton College. On the north the Chiltern hills form a splendid background, with Burnham Beeches, Stoke Pogis, and Slough in the forefront. To the east is seen the smoke of London, and on a clear day the towers of the Crystal Palace are distinctly visible, and to the south and south-west the sky line marks the great forest of Windsor for many miles.

The flower garden is situated on the east side of the Castle, and is about 4 acres in extent. It is surrounded by a broad terrace walk, with an embattled wall as a boundary (fig. 105), most of the embrasures being mounted with miniature cannon. The body of the garden is sunk about

12 feet below this terrace, and is therefore seen to the best advantage by the public, who, as previously mentioned, are admitted on Saturday afternoons, and sometimes on Sunday, by the Queen's commands, when also the two bands of the regiments staying at Windsor play here for a couple of hours to the delight of the numerous visitors.

The lower body of the garden is divided by broad walks into four sections, a handsome fountain occupying the central position. The style in which it is formed and furnished may be appropriately called a mixture of Italian and English. It is rich in statues and other beautiful and valuable works of art in marble. A series of large beds are planted along the boundary of the garden at the base of the green bank which supports the terrace walk, with a number of choice evergreen shrubs from 5 to 8 feet high, such as Golden Holly, Golden Thuias, Cupressus, Retinosporas, Irish and other Golden Yews, all moderately cut into perfect pyramids and bushes (fig. 106, page 551).

At the time of our visit these were rich in their young golden growth, producing a striking effect. This style of judiciously introducing gold and green pyramids is followed throughout the body of the garden, only in more moderate proportions, for giving adequate room between the shrubs for flowering plants in spring and summer. The introduction of these groups of shrubs helps to warm the garden, and as it were in some measure to counteract the grey, cold, and severe aspect of the Castle, which forms its massive boundary on the west:

About 50,000 plants are used in furnishing this garden for both a spring and summer display. Most of the plants used for spring are raised from seeds, at little cost, and include the following: Dark and yellow Wallflowers, purple and white Honesty, blue, white, and yellow Violas, *Myosotis dissitiflora*, *Aubrietia*, *Silene*, yellow *Alyssum*, *Polyanthus*, Primroses, Daisies, and Pansies, with which are associated Hyacinths, Tulips, and other bulbs. The system adopted in planting is to aim at massing the different kinds in harmonious colours in order to produce telling effects from the terrace and the Castle windows, rather than planting in rows and small groups for close inspection. That the desired result is attained is beyond question, as a finer exhibition of spring flowers than was seen in May it is difficult to imagine; while those who have inspected the garden in summer will admit its varied charms.

Much more might be said of this beautiful garden, with its numerous flowers, and of the old orangery which forms its northern boundary, and which is furnished chiefly with Palms, Camellias, and in winter is used for preserving tender bedding plants (which it does without fire heat, its walls being so thick, and its shutters so closely fitted), as might also be said of the terrace wall next to the Castle, covered as it is with Magnolias, Banksian Roses, Pomegranates, *Ceanothus*, Roses, and many other beautiful climbing plants; but we must be moving on, as we have much to see and to say.

QUEEN VICTORIA'S WALK.

Retracing our steps a little way we stand on the south side of the Castle near the Grand Entrance, and face the Long Walk with its splendid avenue of Elms. We turn to our left and follow the wall of the flower garden on the Park side. In front of this wall, which is beautifully clothed with Ivy, is a plantation of evergreens and hardy flowering trees and shrubs; the latter mostly planted about two years ago, about 600 trees of about fifty species, and include Almonds, Mountain Ash, double Cherry, Crabs, Laburnums, *Acer Negundo variegata*, Lilacs in variety, Weigelas, Forsythias, *Arbutus*, *Philadelphus*, *Spiræa*, in variety, *Viburnum*, *Halesia*, Magnolias, *Rhus cotinus*, Sweet Briars, Snowy Mespilus, Judas Tree, Bird Cherry, and many others too numerous to mention. These will be very beautiful when well established in a few years time. They will be seen to great advantage from the flower garden terrace, and from the Queen's apartments in the Victoria tower, which overlooks all (fig. 106, page 551).

On the right hand as we go along is a wide expanse of lawn of about 9 acres, kept in the best of order, as are all the other parts. Many handsome deciduous trees of modern planting are to be seen, the most conspicuous being a handsome Copper Birch. On the left hand as we go along we see next the terrace wall many indications of the Queen's love and care for her pet dogs, not only when they are alive, but also when they are gone, in tiny monuments of marble and bronze placed over their graves and partly hidden by shrubs. Here we also pass by a splendid *Cedrus deodara* planted by the Prince Consort a few days after the Queen's marriage; and at the north-east corner of the terrace one of the finest trees in the kingdom of *Kœlreuteria paniculata*, which shows its noble head of yellow flower above the embattled wall.

Proceeding a little farther we come in contact with the high portion of the slopes.

The Queen Victoria walk or drive passes along near the edge of the great natural terrace, and from it glimpses are obtained, between the trees, of the deep picturesque dell below. On the park side of this walk are to be planted at wide intervals a number of trees of the blue-tinted Mount Atlas Cedar, *Cedrus atlantica glauca*, which are destined to become historical, for they are to commemorate the great reign of their Royal owner, which is now being so heartily celebrated in all parts of her vast dominions. The Mount Atlas Cedar is a beautiful hardy long-lived tree, the glaucous form growing as freely as the green, and is singularly attractive. The young trees are established in baskets for the purpose of insuring their growth when planted in the summer. They will add a distinct feature of interest and beauty to the Royal demesne.

THE SLOPES OF WINDSOR.

Pass we now to the lower ground. For quiet, secluded, romantic scenery the slopes of Windsor are justly famed. This is really a woodland garden, extending from the extreme northern end of the Castle, near the 100 steps leading from the town to the Castle, clothing the steep banks of the Castle heights, and the ground on the flat below for nearly a mile, with magnificent trees of great size and antiquity. They are mostly Beech, Chestnuts, Elms, Oaks, Planes, with many Scotch and ordinary Fir trees. The level on which we are standing is upwards of 200 feet higher than the lower portion of these grounds. As there is a shady and rural walk on the top edge of this precipitous bank we will walk

quietly along, noting features of interest on the way. The first matter to arrest attention is the soothing sound of falling water. This is from a small cascade in the depths below, the water afterwards running through the grounds in a beautiful winding stream, soon finding its way by the side of the Lime avenue to the Thames, from whence it was diverted higher up the river at great cost many years ago. Here also is seen in the distance a summer house, with a garden enclosed, which at one time was frequented by the young Princes and Princesses, who there played and planted their flowers. We cannot pass by without noting the beautiful condition of the carriage drives and walks which wind through and intersect these grounds in all directions.

A broad drive cuts through the steep banks of the slopes and across the walk we are on. This is the private carriage drive leading from the Castle to the South-western lodge and station. By the side of this drive in the bank are formed some wonderful caves, such as would delight the hearts of children to play hide-and-seek in. Crossing over this drive we proceed along the ledge of the slopes, still under the shade of handsome trees, admiring on both sides the many flowering trees and shrubs, with myriads of Primroses peeping out of the grass banks, until we come to a sort of subway constructed of chalk, flints and rough stones, cleverly formed with a curve, in order to hide from view as long as possible the object to which it leads—a pretty rock garden, and which it succeeds in doing admirably.

This garden was formed and planted many years ago under the personal care and supervision of her Majesty and the Prince Consort. It is, as it were, cleft out of the steep bank, and planted with alpine trees and plants; at the base below is an irregular artificial basin of water, fed by a stream or waterfall running down the bank, and immediately above this is a curious grotto, the inside walls of which, as well as the roof and floor, are formed by myriads of small pebble stones fixed in cement. What a work of patience this must have been! Altogether this is a most interesting rock garden, appropriately kept in a semi-wild state.

QUEEN ADELAIDE'S COTTAGE.

Still proceeding, we come to another pleasant surprise in the beautiful gardens and cottage named after H.R.H. Queen Adelaide. This secluded and quiet retreat is at the extreme end of the slopes from the Castle. The cottage, which is of a beautiful design, rests against the bank, looking over the park towards the River Thames and Datchet. It has about it a lovely little garden of the old-fashioned sort, with high hedges, and many nooks, corners, and surprises; here also is the cottage of the

Foreman of the Slopes, clothed as an arbour by a luxuriant old Vine, from the Grapes of which many gallons of excellent wine have been made.

Also, close by, is the historical and interesting Lutheran Beech, now of large dimensions, and in perfect health. It is said to have been raised from the Beech tree near Altenstein, in the Duchy of Saxe-Miningen, under which tree Luther was arrested at the time of the Reformation. The little offshoot was brought to England by King William IV. when Duke of Clarence, and planted by Queen Adelaide

FIG. 105.—TERRACE GARDEN AND EMBATTLEMENTS.

in the gardens of her residence at Bushy Park. Her Majesty bequeathed the tree to H.R.H. Prince Albert, with the request that it should be transplanted in the grounds of Adelaide Cottage, which was done in 1850. The original tree at Altenstein succumbed in July, 1841. It is to be hoped that the present beautiful one will long live and flourish to perpetuate so interesting and historical an event.

Here in a separate enclosure, entirely hidden from view by huge Yew hedges are situated the glass houses and pits in which the thousands of summer bedding plants are grown. A short rise up a broad avenue takes us out of this delightful garden, and also out of the slopes, and we stand again in the open Park not far from the kennels of the Queen's pet dogs, and from where, to the right, we again have a glimpse of the east side of the Castle towering in solitary grandeur with the sky as a background.

BEAUTIFUL AVENUES AND NOBLE TREES.

Crossing from the slopes to Frogmore we enter one of the most important avenues in the Park, running from east to west from the River Thames to Windsor. There are many of these great avenues round the Castle, and the most delightful of all is the old Lime avenue leading from the slopes to the river. In the summer this is a perfect Gothic arch half a mile long of dense green foliage. Hereabouts also are some notable trees. Immediately to our right is a Cedar of Lebanon, planted by the late Mr. Thomas Ingram less than fifty years ago, and which

deserves notice as showing to what size and dignity this handsome Cedar attains in a comparatively short space of time. It is now 50 feet high, and has a spread of branches of 63 feet, the girth of the stem 6 feet from the ground being 11 feet.

Another handsome tree is also noticeable—a Wellingtonia, planted to commemorate the confirmation of H.R.H. the Princess Royal of England. This is the first Wellingtonia planted at Windsor, and is probably one of the first introduced into this country. By the drive leading from the kennels to the Castle is the finest Oak associated with Windsor Castle (if we except William the Conqueror's Oak in the Great Park). How old the veteran is no one knows, but judging by its ancient and hoary appearance it may be safely conjectured that it is as old as the Conqueror's Oak, and therefore dating back at least to the Norman period. Its girth at 4 feet from the ground is 36 feet. Near it is one of the handsomest of the many thousands of Elms round Windsor. This is about 120 feet high, with a girth of trunk 4 feet from the ground of 26 feet. This is a splendid tree, in perfect health.

THE ROUNDABOUT GARDEN.

Passing along on the way to Frogmore House Gardens we arrive at the "Roundabout Garden." This has been formed in an open position in the park, not far from the Castle, by planting a round belt of trees, those on the outer boundary consisting of now large and well-grown specimens of scarlet Chestnuts, Limes, Oaks Evergreen and English, Birch, Hollies, Araucarias, and many species of Pines, having a splendid face to the interior of huge bushes of Rhododendrons, Lilacs, and Thorns, with an old specimen of the Judas Tree just opening into bloom. In the centre of the garden is an immense bed of Rhododendrons and standard Roses. This unpretentious little garden possesses in combination the charms of perfect seclusion, quietness, repose, and simplicity, with the brightness and fragrance of flowers. So we thought as we admired it from a rustic arbour it contains embowered trees.

ROMANTIC GROUND.

From the garden just left the Fairy Pit Pond is soon reached. This is now a piece of artificial water used for skating on in winter, and close to Herne's Oak of historic memory. There are few things connected with Windsor which have excited greater interest than the question of the position and identity of Herne's Oak. It is scarcely necessary to say that the interest attached to the point is founded on a certain tradition and the allusion to the employment of that tradition in Shakespeare's play, the "Merry Wives of Windsor"—namely, that Herne, one of the keepers of the Forest, was to be seen after his death, with horns on his head, walking by night round about an Oak in the vicinity of the Castle. It is said that, having committed some great offence for which he feared to lose his situation, he hung himself on this Oak, which his ghost afterwards haunted. The first reference to the tradition occurs in the fourth scene of the fourth act, where Mrs. Page says—

"There is an old tale goes that Herne the hunter,
Some time keeper here in Windsor Forest,
Doth all the winter time at still midnight
Walk round about an Oak with ragged horns;
And there he blasts the tree, and takes the Castle,
And makes milch kine yield blood and shakes a chain
In a most hideous and dreadful manner."

The site on which the old tree stood is now occupied by a healthy young Oak, planted by her Majesty in order to perpetuate so interesting a tradition. Near this spot are the dead trunks of two old Oaks, supported in position by props, and which may be fairly supposed are twin sisters of the old haunted tree.

DRIVES AND DUTCH GARDEN.

A few yards from this romantic ground we come on to the main drive leading from the Long Walk by Frogmore House to the Royal kitchen gardens, and also to Old Windsor, and to the right of us is another drive communicating with Frogmore House and the Castle. Speaking of drives and walks we may here say that there are twenty-five miles of walks and drives in the Royal Gardens department at Windsor, and no better can be found in the kingdom.

As we stand on the drive at this spot the Queen's little entrance gate to Frogmore House Gardens is immediately before us. It is called the Queen's Gate. Before entering a glance is taken to the left, and there for a distance of 200 yards, close to the drive, and separated from it by a low bank of Laurels only, is seen one side of as perfect a specimen of an old Dutch garden as it is possible to conceive, with its immensely thick Yew hedges (fig. 107, page 552), supported and lighted up by some of the finest standard trees of *Acer Negundo variegata* we have seen. Further on this drive we pass the east front of Frogmore House, and the eastern boundary of the grounds, faced by scarlet and white Chestnuts in full bloom and altogether beautiful.

Frogmore House Gardens.

We believe this is the first time that permission has been given for these delightful old gardens (in which her Majesty takes so great an interest, and with which the Queen's whole life has been so closely associated) to be described and illustrated to any extent desired. For this privilege we are most grateful; but however loyal the pen and pleasant the task, a difficulty is felt in adequately portraying the many fascinating and interesting features of this cherished enclosure and beautiful haven of repose for the living and the long-mourned dead. Before entering on a description a few brief words relative to the history of the gardens may prove of interest.

Among the Crown lands sold after the Civil War was Frogmore, which came into the possession of George Fitzroy, Duke of Northumberland, whose widow, the Dowager Duchess, died here at a very advanced age. About 1748 Frogmore was purchased by Sir Edward Walpole, K.B., who made many improvements in the gardens, and to whom we are no doubt much indebted for the wealth of magnificent and interesting deciduous trees found therein. Queen Charlotte purchased the lease of Frogmore, when it became her Majesty's favourite residence, and subsequently that of her Royal Highness the Princess Augusta; then afterwards for many years of her Royal Highness the Duchess of Kent; and since her mother's death it has been in the occupation of her Majesty the Queen. Their Royal Highnesses the Prince and Princess of Wales lived here for a short time, and this was the birthplace of their first-born child—the late Duke of Clarence, whose pathetic and tragic end is still alive in the memory of all. It was also the home of their Royal Highnesses Prince and Princess Christian before they took up their residence at Cumberland Lodge.

Entering the garden at the Queen's little gate previously mentioned, immediately on the left is the quaint and interesting old Dutch garden with its immense Yew hedges and beds of old-fashioned herbaceous plants, the whole kept as near as possible in the same fashion as it was in those far-off days of William and Mary. To the right is the sheltered and cosy garden belonging to Frogmore Cottage—now the residence of her Majesty's native Indian Secretary. At a turn of the walk a few yards further we come upon a beautiful lawn, almost of an oval shape, bounded on three sides by a belt of high trees, giving one a momentary impression that we have the whole of the garden before us, so cleverly are the other portions hidden from view. In the centre of this lawn is a beautiful Indian marble kiosk, sent to the Queen by the first Governor-General of India, Lord Canning. To the right are the glass houses in which plants for the decoration of Frogmore House and gardens are grown, and in which was observed the bright and elegant old *Begonia fuchsioides* growing and flowering in great luxuriance, trained over pillars and arches, loaded with its beautiful coral-like heads of drooping flowers.

The plan (fig. 108, page 553) of these beautiful grounds is from the pen of Mr. Harry Thomas, a promising student in the Royal Gardens, Kew.

THE LAKE AND ISLAND.

Passing these houses, and skirting the belt of plantation to our right, we have a charming panoramic view of a portion of the garden. Immediately in front of us is a large, well-wooded island, and at its base a first peep of the beautiful lake, which plays so important a part in the embellishment of these delightful grounds, is obtained. Looking to the left along a portion of the lake the eye first rests on what appears a small Gothic ruin, nestling under the branches of an immense Cedar of Lebanon, and guarded in front by an equally ancient and noble giant Plane tree. Near this is a small rustic bridge, crossing a neck of the lake, and over which hangs in a caressing-like way the drooping branches of a Babylonian Willow.

Glancing a little farther—still over the lake—we have a peep at another pleasant lawn, flanked on the right and left by high banks of Rhododendrons, flowering Chestnuts, pink and white Laburnums, Bird Cherries, Thorns, Lilacs, and other flowering shrubs. On this lawn are growing many single specimen trees of great rarity and beauty, some of them perhaps the finest examples of the kind to be seen in any garden. Very conspicuous is an immense column-like tree of *Libocedrus decurrens*, 65 feet high, of great girth, a splendid specimen without fault or blemish. It was planted in 1857 by the Princess Hohenlohe. It is shown in fig. 109, page 555, with its reflection in the water, and a glimpse is also had of the west front of Frogmore House.

Near this is a singularly fine example of the Maidenhair Tree

(*Salisburia adiantifolia*). In form this may be said to be a blunt pyramid, 75 feet high, with a girth of stem of 9 feet at 3 feet from the ground, and so heavy are some of its branches that they have been, for a long time, banded together to the trunk by chains for safety. Close by is a fine specimen of *Thuia borealis*, 36 feet high, and in perfect health, also *Cupressus Lawsoniana*, upwards of 40 feet.

After viewing the left part of the garden we turn for a moment to the right. Here we have also the placid waters of the lake nestling against the banks of the previously mentioned wooded island, and near the walk is an immense tree of the Deciduous Cypress, measuring 75 feet high, its stem being clear of branches to the height of about 40 feet. A little farther to the left, on the bank of the

same time; and on the same date *Cupressus Lawsoniana*, by H.R.H. Princess Louise; and also on the same date *Cupressus Lawsoniana* was planted by H.R.H. Princess Beatrice.

Cedrus atlantica was planted by Prince Albert Victor of Wales in 1873; *Pinus pinsapo*, by their Royal Highnesses Prince and Princess Christian in 1867; *Picea lasiocarpa*, by Princess Thyra of Denmark in 1875; *Picea Nordmaniana*, by H.R.H. the Duchess of Edinburgh in 1874; *Quercus Suber* (Cork tree), by H.R.H. the Princess of Wales in 1873; the same by her Majesty the Queen of the Belgians at the same time; *Thuia gigantea*, by Prince's Louise of Hesse in 1864; the same by Prince Louis at the same time; *Cupressus sempervirens stricta*, by the Queen in 1864; *Cupressus Lambertiana*, by Prince Arthur, 1864;

FIG. 106.—VICTORIA TOWER AND FLOWER GARDEN (page 548).

lake, is the best proportioned and finest-looking Cedar of Lebanon in the garden, although not the largest, and close by under the shade of this tree is a simple looking rustic summer house, with a thatched straw roof, looking so cool and restful on this hot summer morning.

ROYAL MEMORIAL TREES.

Further on in the same direction we come to a piece of lawn, on the north-west side of the Prince Consort's Mausoleum, on which are planted a large number of specimen coniferous and other trees by members of our own or other Royal houses, a few of which may here be mentioned. *Abies Pattoniana*, planted by her Majesty the Queen of Denmark in 1875; the same variety by her Majesty the Empress of Germany in 1876; *Cedrus deodara*, a magnificent specimen, planted by H.R.H. the Duchess of Kent in 1850; *Cupressus funebris*, by Princess Adelaide of Hohenlohe in 1853; *Cedrus libani*, by H.R.H. Prince Christian in 1867; *Cupressus Lambertiana*, by H.R.H. the Prince of Wales in 1864; the same by his Majesty the King of the Belgians at the

Thuia gigantea, by Prince Leopold, 1864; *Sciadopitys verticillata*, by Princess Louise Margaret of Prussia; *Wellingtonia gigantea*, by Princess Hohenlohe, 1857; *Abies Albertiana*, by Princess Victoria and Elizabeth of Hesse, 1887.

Two trees of *Pinus Laricio*, brought by the Queen from Hyères, were planted by Princess Ena of Battenberg and Prince Alexander; *Pinus parviflora*, by H.R.H. Prince Henry of Battenberg, 1885; *Picea lasiocarpa*, by Princess Helen of Waldeck, 1882; *Picea cephalonica*, by the Duchess of Kent, 1851; *Quercus Ilex*, by her Majesty the Queen, 1864; the same variety by the Czarevitch (now Emperor of Russia), 1894; *Salisburia adiantifolia* (a cutting from the large tree previously mentioned), by her Grand Ducal Highness Princess Alice of Hesse (now Empress of Russia), at the same time; English Oak planted by the Queen, June 20th, 1887, to commemorate her Majesty's Jubilee. Can elsewhere in the whole wide world be found such a collection of Royal memorial trees as this? But we have not quite done.

A little nearer the Mausoleum are two handsome *Wellingtonias*,

with a history of special interest. These trees were planted in the first instance in the grounds of the Royal Horticultural Society's Gardens at South Kensington, one by H.R.H. the Prince Consort on June 5th, 1861, on the occasion of the first opening of the garden and the other by the Queen on June 24th in the same year—the year, it may be remarked, of the lamented death of Prince Albert. On December the 15th, 1869, they were removed from South Kensington to Frogmore Gardens, and on the 17th were planted here by her Majesty near the Prince Consort's Mausoleum. One of the trees died in August, 1870, and another was planted in its place by the Queen in the December of the same year. The history of these two handsome and perfect trees is thus invested with a pathetic and interesting reminiscence as regards H.R.H. Prince Consort, her Majesty the Queen, and the Royal Horticultural Society. These interesting Wellingtonias are seen in the background in fig. 110, page 557, the large tree in the foreground being *Picea Nordmaniana*, planted by H.R.H. the Duchess of Edinburgh, in 1874.

Still proceeding on our way, we come to the main entrance gate leading to the Royal Mausoleum, and, turning to our left, we pass through many of the previously mentioned Royal specimen trees, and under the branches of an immense Cedar of Lebanon. This tree has a straight trunk rising to the height of 80 feet, and nestling as it were against a portion of its branches is the Royal Mausoleum—a temple embalmed with ever sacred memories, at the portals of which as we pass by we can only pause for a moment with reverent feelings and respectful sympathy.

To the left we cross a little stone bridge, from where we have a charming view of the lake, and immediately find ourselves on an island, a most secluded and quiet retreat, forming a sort of glade, with many single specimen trees of Wellingtonias, Libocedrus, Magnolias, and Sweet Chestnuts, the whole banked round its boundary on three sides by Rhododendrons, and on one side by the lake. Still proceeding we come to another bridge taking us from the island towards the beautiful mausoleum of H.R.H. the Duchess of Kent, the Queen's mother. This stands on a high elevation embowered in many trees of luxuriant growth (fig. 111, page 559).

Again passing along by a walk to the right, by a circuitous route, having the high mound on which the Mausoleum is built to our left, and the lake to our right, we arrive at another cosy summer-house, and immediately afterwards we stand before the west front of Frogmore House, a homely, comfortable, unpretentious, English-looking mansion, the exterior being painted a light grey colour. In front of the mansion a splendid general view is obtained of the grounds, the lake, and the park beyond. A smooth soft lawn, of considerable extent, gently slopes down to the lake side, and the lake here seems to fold in its embrace, as it were, a richly wooded promontory. On the left it is spanned by an artistic iron bridge, and on the right it seems to lose itself behind the leafy mound of the Duchess of Kent's mausoleum. Still to the right we have one of the beautiful lawns previously mentioned, with its unique specimen trees and beds of Roses, Ghent Azaleas, and Ivy basket beds by the walk side, which are planted with spring and summer bedding plants. On the left are some glorious deciduous trees, now in the full beauty of their young leafage, under which, in the distance, can be seen a glimpse of Her Majesty's tea rooms; but we must not anticipate. From here we also have a glorious view of Windsor Great Park and its giant forest trees.

Here, also, at the south-west corner of the house, is a simple little flower garden on the turf, and which in spring and summer is planted with bright flowers. Very few of what are called summer bedding plants are grown at Frogmore House. With such wealth of flowering trees, shrubs, and herbaceous plants, verily few are wanted. Now

let us leave the walk and cross over the lawn under the shade of some giant Elms and Beeches in the direction of the Queen's tea rooms, noting on our right as we pass a refreshing and bright glade of Rhododendrons. It is from here that the view representing the tea rooms has been obtained, also the first view of the two veteran Evergreen Oaks, said to date back to the time of the Crusaders (fig. 114, page 563).

These are magnificent trees, and from the distance appear as one, the circumference of their branches measuring upwards of 100 yards. They are in perfect health, and it is underneath these two old veteran Oaks that her Majesty frequently takes breakfast and tea in the summer time. It is in truth a charming spot, destined to become historical.

Thus comes to an end a mere glimpse of this much-cherished, beautiful, and delightful garden. We do not know which to admire the most as we pass through—whether the magnificent forest trees or the glorious collection of flowering trees and shrubs, and the specimen Coniferae, the lawns, the lake, or the exquisite way in which this 36 acres of garden is laid out and the perfection of order in which it is kept. It is not any one of these, but the "perfect whole," forming as it does in harmonious beauty one of the most lovely, peaceful, and restful gardens it has ever been our privilege to look upon.

We are now distant only a few minutes' walk from the Royal kitchen gardens. Noticeable on the way is a row of Medlars, beautiful trees, established on Thorns many years ago, presumably by the late Mr. Ingram. Crossing a new orchard of high promise we are within the garden walls, and in the commodious home of the head gardener find welcome rest after a morning's stroll that will haunt the memory, if life and health be spared, for many a year to come.

FIG 107.—DUTCH GARDEN (page 550).

The Royal Supply Gardens.

WHAT are known as the Royal kitchen gardens are such, and very much more. Not only is produce of all kinds, and of the best quality, grown in enormous quantities for culinary purposes in the various departments of the Queen's garden, but the demand for dessert fruit is of corresponding magnitude, while the requirements for plants and flowers are so great that the extent can scarcely be fully comprehended. Everything that a well-appointed, well-equipped, and well-managed garden can be made to yield is provided here, and transmitted to wherever the Queen and Court may be in residence, whether at the Castle, Buckingham Palace, Balmoral, Osborne, the South of France, or elsewhere. Packing may be said to be always in progress. In the ordinary routine the work is great, while an idea of the extent of it on extraordinary State occasions, as at Buckingham Palace, can perhaps be best formed from the fact that a special train is occasionally chartered for the conveyance of plants and other products on those occasions—the greatest and most varied supplies from, so far as we know, the greatest private gardens in the world, all planned and completed within the period of the great reign which is now in the course of celebration.

Before the present gardens were constructed the fruit and vegetables required by the Queen and the Royal household were grown at various centres, many of them wide distances apart. They included the Royal Gardens, Kew, Hampton Court, Kensington Palace, Maestricht (where now stands a portion of the station of the South-Western Railway at Windsor), Cranborne, Cumberland Lodge, and elsewhere. In

those days the delivery of supplies to the Castle and Buckingham Palace was effected by road, being collected from the various centres three times a week by horses and vans kept for this purpose. Under these adverse conditions the supplies were often intermittent, the management costly, and the supervision inefficient, as the head gardener in those days lived at Kensington.

Eventually a committee was appointed to consider the question of supplanting this clumsy and antiquated system by a new, efficient, and central supply garden near Windsor Castle. The issue of this commission resulted in an Act of Parliament being passed authorising the leasing or dismantlement of those various scattered gardens, and the construction of the present Royal gardens was sanctioned to commence about the year 1843.

SITE AND SOIL.

The site chosen in the Home Park is on the extreme edge of the Park, south-east of the Castle, and distant from it about a mile and a

quarter. It is immediately below Frogmore House pleasure grounds, and bordering on the village of Old Windsor. That the site is the best in many respects that could be found there can be no doubt. It is as near the Castle as it could be judiciously placed on account of so much rough and heavy work which must always be associated with the working of such an immense garden. It is bounded at its lower end on both sides by a public road, one from Old Windsor to New Windsor (Old Windsor is said to have been a Royal residence before the present town of Windsor was in existence), and the other from Old Windsor to Datchet, thus affording all possible facility for the heavy carting of fuel, soil, and manure without having to traverse much of the private grounds. But from a strictly cultural point of view the garden lies too low, being only a few feet higher than the Thames, from which it is distant about 250 yards. This low position exposes the garden to much dampness and fogs in winter, and fruit tree blossom and early vegetables to damage from frost in spring.

- 12, Lake.

Another objection may be stated—namely, the composition of the soil—a heavy marl, varying in some parts to strong clay. Even now, after having been thoroughly worked and liberally manured every year for half a century, it is most stubborn, and can only be brought into proper condition to receive seeds and crops after the expenditure of much labour and time.

Passing Frogmore House and noting on the way a new Apple orchard of 4 acres, and a recently rejuvenated old orchard, we proceed through a thinly planted avenue of Wellingtonias, planted about forty-five years ago. Opposite the garden entrance a glance is had of the Evergreen Oak avenue (leading from the Lodge to the Thames) planted ten years ago by the Queen and members of the Royal Family to commemorate her Majesty's fiftieth year on the Throne. The Evergreen Oak is a slow-growing tree, and it will be a long time before this makes an imposing avenue. Still the trees are in excellent health and growing satisfactorily. We are now at the garden entrance lodge, this and the pillars being densely clothed with Ampelopsis Veitchi; but before passing the porter, dressed in green and gold, it may be well to give some idea of the size of the kitchen gardens and their general arrangement.

AREA AND TERRACE.

The area of garden ground secured in the first instance was 31 acres, all of which were enclosed by a substantial and well built wall, 12 feet high, protected by a coping with a projection of 4 inches on each side. This boundary wall measures from east to west 352 yards, and from north to south 285 yards. The great length from E. to W. gives the garden a splendid exposure to the sun from morning to night. Its position is south, with a few points to the east. This large enclosure is intersected by other walls of the same height, forming in fact six separate gardens, all of course communicating with one another.

After the completion of this garden it was soon found that this area was insufficient, and 10 acres more were added on the south side, and after a time 10 more acres were joined to the west side, so that with the 3 acres of kitchen garden (walled in) at Frogmore House, the extent of the Royal kitchen and fruit gardens amounts to upwards of 50 acres; and even this large area is found to be insufficient, much fruit and many vegetables often having to be bought. The construction of the garden, not including the great additions which have from time to time been found necessary, amounted to about £50,000.

On entering the lodge gates the first object that presents itself to the spectator is an imposing terrace 352 yards long by 25 yards wide, having a wide carriage drive in the centre, bounded on each side by a broad space of turf, on which are planted Roses in round and oblong beds. Between these beds, on both sides, are many bell-shaped wire trellises about 9 feet high and 7 feet wide, all covered with climbing Roses—Crimson Rambler, Carmine Pillar, W. A. Richardson, Bennett's Seedling, Aimée Vibert, and other varieties which help to make a charming picture in the summer time.

On the right of this noble terrace (about half of which is shown in the illustration, fig. 115, page 564), and parallel with the drive, is constructed the chief range of fruit houses the whole length of the terrace, broken only in the centre by the head gardener's house into two ranges—one called the East and the other the West. In these ranges are nine vineries, four Peach houses, and one large Rose house, besides many connecting corridors, each having a door communicating with the terrace, and each corridor planted either with Grapes or Peaches. Behind the wall, against which this long range of lean-to houses are built, are all the garden offices, such as bothies, bath rooms, library, stokeholes, Mushroom houses, packing and potting sheds, and fruit rooms. In front of these buildings is the little town of glass houses and pits devoted to the growth and forcing of fruits, flowers, and vegetables. This area covers about 8 acres, and is enclosed by walls 12 feet high.

On the left hand of this great south terrace—along which her Majesty frequently passes in the course of her afternoon drives, are specimen Thuias, Irish Yews, Golden Hollies, and Cypresses, many of them 30 feet high. These are flanked on the kitchen garden side by a low hedge of China and W. A. Richardson Roses, and also by a line the full length of the terrace of fine specimen pyramidal Pear trees about 15 feet high, and removed here only three years ago. Parallel with these are two flower borders, each 120 yards long by 24 feet wide, one containing a collection of Hybrid Perpetual and Tea Roses, the other planted two years ago with the best known varieties of hardy plants for cutting purposes and for pleasing effect. Southward from this terrace and borders extends the kitchen garden and hardy fruit trees, to be referred to in due course, another section of this great establishment claiming prior attention.

THE GLASS DEPARTMENT.

So extensive is this, that only the salient features can be noted, and a few practical points in routine briefly indicated. The terrace ranges previously mentioned, and partly shown in the illustration (page 564), were built by Messrs. Clarke & Hope of Birmingham, upwards of fifty years ago, the materials used being iron and copper. The houses are light and elegant, and when it is said that they are from all appearance as good as ever they were, it speaks well of the materials used and the workmanship of those days. A prejudice exists among many gardeners against iron and copper houses, in which it is clear that Mr. Thomas does not share, and as a matter of fact the heavy crops of fruit obtained from them annually speak forcibly in their favour. Let us take a short survey of the fruit grown under glass, and see how the houses suit the different kinds.

GRAPE CULTURE AND SUPPLY.

Grapes form an important part of the Frogmore fruit supply, and of vineries there are eleven, many of them of large size, and none of them small. For the last two seasons the year round has been spanned with Grapes—an everyday supply without a break. The summer daily demand is seldom less than 15 lbs., sometimes rising, with large parties, to upwards of 100 lbs. For a State ball or concert at Buckingham Palace 60 to 80 lbs. are needed. Fruit at one time used only to be furnished with luncheon and dinner, now it must be forthcoming at every meal, and in quantities too—a healthy sign this for gardening, which is spreading far and wide. When it is said that about 5000 lbs., more or less (according to the season) of Grapes are grown annually for her Majesty, including the returns from the old Vine at Cumberland Lodge and the one at Hampton Court, it will be readily understood that heavy crops of the best quality must always be forthcoming.

The first vinery is started during the last week in October or early in November, according to the ripeness of the wood, and also dependent on the quantity of Grapes in stock. The temperature is regulated according to the external conditions of the weather. If mild, the Vines are given a temperature of 55° to start with, rising gradually, as growth advances, until about the first week in January, to 70° at night, and this temperature is practically maintained until ripe Grapes are cut, during the last week in March or the first week in April, the earliest on record here being March 14th, four years ago. The varieties grown for the purpose of early forcing are Black Hamburgh and Foster's Seedling. The Vines are pruned on the long spur system, each lateral being cut, not necessarily to the lowest, but to the first good bud from the base. There are thousands of Vines over the length and breadth of the land that would yield much better crops than they do if pruned on this common-sense method, instead of being cut to the lowest bud, whether it be good or bad.

The second vinery is planted with the same varieties and pruned on the same principle. It is started about the middle of November, and ripe Grapes are cut from the middle of April to the end of May. This is a larger vinery, being 120 feet by 15 feet wide, and out of it are usually cut during May 700 lbs. of fruit. One half of the Vines are ten years old and the others about thirty years, the old ones looking as well and carrying equally heavy crops of good quality Grapes with the younger ones.

The third vinery is started December 26th, and ripe Grapes cut at the end of May and in June. This house was formerly used as a Pine stove, with one Foster Seedling Vine planted against the back wall for shading the path. The Pines were removed to other quarters a few years ago, and the old Vine, once the restrictions were removed, soon covered the roof with splendid wood and foliage, and now produces annually not less than 200 lbs. of first-class Grapes—a beautiful sight, and eloquent proof of the soundness of the principle of extension.

The fourth vinery is 75 feet long by 15 wide, planted with Black Hamburghs, started on January 15th, and now (20th May) ripening a very heavy crop of excellent Grapes, estimated to weigh upwards of 400 lbs., and intended for use during the Diamond Jubilee celebrations. These Vines have been planted twenty years, and have borne heavy crops year after year without a single failure. They are always pruned to the first good bud, and young shoots laid in to take the place of any spurs which may have to be cut out the following winter.

Next in rotation comes a house of Madresfield Court, Golden Champion, and Duke of Buccleuch, all looking well and carrying heavy crops of fruit, also intended for the Jubilee time. This house was planted 1st of July, 1893, with young growing Vines. At the end of September the roof was covered with splendid growth, and the following year three or four bunches of Grapes were taken from each rod, and they have since produced excellent results. A faint idea of these Grapes may be obtained from the small photograph taken long before they were ripe (fig. 116, p. 565).

Next comes the Muscat house, planted the same day as the last-mentioned, and treated in the same way, with equally successful results, and the Vines are now bearing a splendid crop of useful Grapes.

The remainder of the vineries are devoted to the cultivation of late Grapes, for which there is a large and increasing demand. The varieties best suited for this purpose are found to be the Muscat of Alexandria, Black Alicante, Gros Colman, Lady Downe's, West's St. Peter's, and Raisin de Calabre. Other varieties are grown, but those named succeed the best.

The Vines in these houses vary in age from one to thirty years, and all are more or less grown and worked on the extension system. Soil for the Vine borders is obtained from the Great Park. It is of good quality, having plenty of fibre; to this, and also to the fact that red spider is unknown on the Vines at Frogmore, must be attributed the heavy crops of excellent fruit annually grown.

PINES AT HOME.

Frogmore has been the home of the Pine Apple since the formation of the gardens, and much has been written from time to time during the past fifty years on the success attending its cultivation in the Royal Gardens. That that success has not in the least diminished, the splendid condition of the plants and their noble fruits, prove most conclusively. The varieties mostly grown are Smooth Cayenne and Charlotte Rothschild. The method of cultivation chiefly adopted is the planting-out system, and that it is attended with success the photographic illustration (fig. 117, page 567) affords ample testimony, though it does not do justice to the fruits.

The suckers for planting this pit were taken from the parent plant on the 15th of October, and the photograph was taken as well as it could be the following September, eleven months from the time of planting. This shows a greatly improved method of growing the "king of fruits" over that which existed a few years since, when two or two and half years were considered necessary to grow and ripen a good Pine. Half the secret of success lies, as most gardeners know, in planting large healthy suckers.

The number of plants grown in the pit is seventy-five, of which seventy threw up within three weeks of each other, and only five fruits weighed less than 5 lbs., the average being $7\frac{1}{2}$, but some weighed over 9 lbs. The pit (like others) is 40 feet long by 12 feet wide, with two rows of 6-inch pipes back and front. The bottom heat is wholly obtained by the aid of leaves rammed as tightly as possible to a depth of $4\frac{1}{2}$ feet. This body retains a good heat for eighteen months. On this a layer of loam $7\frac{1}{2}$ inches deep is placed, adding a good sprinkling of bonedust.

The soil, which is neither too dry nor too wet when used, is well trodden down, and the suckers, after having a few of their bottom leaves trimmed off, planted very firmly. They are closely shaded until roots have been formed and growth commences, when shading is entirely done away with. Water is given very sparingly in the winter, and the plants give a good account of themselves the autumn following. Other pits are treated in the same way, so that a good succession is always maintained.

Queens are also grown in quantity for spring and early summer supply. Suckers are usually taken off in August, and potted in 6-inch pots, in which they remain until the following March, when they are shifted into their fruiting pots (12-inch). They are plunged in a pit of leaves, with genial bottom heat, encouraged to grow freely, and at the end of summer, when growth is completed, more air is given. In

December the plants are placed in the fruiting pit, where rather more bottom heat is at command, and where all usually throw up early in February, giving useful fruit through the spring and summer months. The number of fruits grown year after year vary a little, but the usual number cut is about 200, weighing from 3 to 9 lbs. each.

At the foot of the Pine pits outside are narrow borders, and it is wonderful how useful these borders are in spring for the growth of early Peas and Cauliflowers, afterwards coming in for Tomatoes in summer and salad in winter. With only fifty acres of land no space can be wasted.

PEACHES AND NECTARINES.

There are seven houses devoted to the cultivation of these. The soil being of rather a heavy texture it suits the Peach admirably, and crops under glass are scarcely ever known to fail. The number of Peaches produced in the houses last year amounted to nearly 200 dozens. The varieties found to succeed best and give the greatest returns are Stirling Castle, Violette Hâtive, Gros Mignonne, Bellegarde, Premier, and Royal George, with Walburton Admirable for late use. A few trees of Waterloo are grown, but as a full crop of this variety is not to be depended on it is only grown for extra early work. These are generally started early in January, and ripe fruit picked in May.

Of Nectarines the earliest by far is Cardinal, the last new one of Mr. Rivers. It is well adapted for growing in pots for early work. A few trees not introduced into heat until January afforded ripe fruit early in May, as many as three dozen fruits on a tree. The second early is Early Rivers, then comes Lord Napier, these never failing to give perfect satisfaction. Pineapple, Elruge, and Victoria follow, with the like result. Of these 120 dozen were picked last year. The Nectarines are grown side by side with the Peaches.

MELONS.

These are in great demand during the summer months, and are in consequence produced in large quantities. They have six houses and a number of pits devoted to their growth, some houses producing three crops a year. A common mistake in growing Melons is to give them too large a body of soil. All the Melon borders at Frogmore have been reduced to half their former size, saving much time, and

requiring much less soil and heating material, while giving far better returns in number and quality of fruits. The varieties esteemed the most are some raised during the past few years in the Queen's gardens. Frogmore Orange comes in first, a white flesh with Orange-like exterior; Royal Favourite, admired for its robust constitution and splendid cropping quality, combined with high flavour. The Lady is thought much of on account of its delicious flavour and robust growth. Many of the older ones are also grown, and experiments often carried out with the view of obtaining improved varieties. The number of fruits obtained varies from year to year, but the average is 550, a daily supply being kept up from April until the end of November. The plants, as a rule, are grown about $2\frac{1}{2}$ feet asunder, and confined to one stem. This illustration (fig. 118, page 568), represents one of these plants, of which there were over fifty more like it, grown in a narrow pit.

STRAWBERRIES.

Forced Strawberries are in great demand during the spring and early summer months, and a daily supply is kept up from early in February until fruits are to be had from warm borders. Forced Strawberries are sent to her Majesty wherever she may be, whether in the South of France

FIG. 109.—LIBOCEDRUS DECURRENS (page 550).

or the North of Scotland; and it says something for the packing that complaints of damage on delivery are rarely heard of at Frogmore. In the season the daily supply is seldom under 10 lbs., and sometimes a great deal more—for a State ball or concert from 70 lbs. to 90 lbs. being supplied. The number of plants forced is 10,000. The weight of fruit gathered varies according to the season, ranging from 50 lbs. to 350 lbs. per month.

The variety which succeeds the best is *La Grosse Sucrée* (fig. 119, page 569), of which 7000 plants are prepared. This Strawberry has one serious fault as a forcer—namely, the luxuriant foliage it produces taking up too much valuable space. *Royal Sovereign* is also freely grown and much liked, with a few of *Vicomtesse Héricart de Thury* for the first dishes. *Royal Sovereign* is found to set its fruit freely in strong heat, and to produce heavy crops. *La Grosse* takes less room in the stoves than *Royal Sovereign*, and is found the very best variety for pot culture, always producing heavy crops of splendidly coloured, well flavoured fruit.

FIGS.

These, somewhat strange to say, have not been hitherto extensively grown at Frogmore, but last year two new houses were planted with trees, and an ample supply of their delicious fruits will soon be forthcoming. *Brown Turkey* is the variety chiefly relied on for the general supply.

CHERRIES.

Ranking amongst the most favoured fruits of her Majesty it is not surprising to find a number of admirably grown trees in pots for yielding, as they do, early and abundant supplies of fruit for the Royal table. Seventy trees are grown, mostly in tall pyramidal form rather than as low spreading bushes.

They are arranged in a span-roofed house running north and south, where plenty of air can be given, this and careful watering being amongst the most important points in their cultivation. The trees are placed in position early in January, ample room being afforded to allow free passage amongst them. They are kept cool, and when in bloom are shaken several times daily to disperse the pollen. Strong heat is avoided until the fruits have stoned, when the same temperature as a Peach house is maintained, and ripe fruit gathered in April. The varieties found most suitable for pot cultivation are given in the order of ripening:—*Belle d'Orleans*, *Early Rivers*, *May Duke*, *Governor Wood*, *Frogmore Bigarreau*, and *Black Tartarian*. The Fig has not hitherto been extensively grown at Frogmore; but last year two new houses were planted, and this delicious fruit will soon be provided in plenty. *Brown Turkey* is the variety chiefly relied on.

For preventing a blank between the forced and open air fruits, a tree or two on the walls are temporarily covered with spare sashes, with the ends matted. In this way the ripening of the crops is materially accelerated and the object in view accomplished.

TOMATOES.

Tomatoes are largely grown and a supply maintained all the year round. For this purpose, and for travelling long distances, no better variety has been found than the *Frogmore Selected*, which received a first-class certificate from the R.H.S. some time ago. Another of Mr. Thomas's raising, and appropriately named *Golden Jubilee*, was similarly honoured at the Temple Show this year. This new variety is regarded as the finest flavoured and most handsome golden Tomato that can be sent to the Royal table. Both are as hardy as any others, and we have seen them succeeding admirably in the open quarters in the summer time.

CUCUMBERS

Are grown in large quantities all the year round, and the variety *Frogmore Prolific*, recently certificated by the R.H.S., is found to be one of the best for all purposes; 1200 brace were cut last year.

PLANT HOUSES IN THE ROYAL GARDENS.

In giving a necessarily brief description of the plants at Frogmore, it should be stated that only those are grown which are serviceable for decoration either for indoor use or affording flowers for cutting. Large quantities of flowers are required daily either at Windsor Castle or for forwarding to Balmoral, Osborne, Buckingham Palace, or wherever the Court is in residence. Here are also prepared all the magnificent wreaths, crosses, and other designs which from time to time are sent by her Majesty on the death of relatives, distinguished people, and many of the Queen's domestic servants who pass away.

The first plant house we enter is a Rose house at the west end of the long range on the terrace. It is 50 feet by 16. The roof is covered by *Teas* and *Noisettes*, some of them being old veterans, with tree-like

stems, all planted in an outside border, the same as Vines might be. They give three crops of flowers a year, the first coming in in January and February—grand blooms and plenty of them. One variety planted twenty years ago deserves special mention, namely—*Pauline Labonte*. It is a charming variety, of robust growth, having large full blooms of a deep salmon colour and deliciously scented. Other varieties on the roof include *Homère*, *Madame Willermoz*, *Safrano*, *Maréchal Niel*, *Rêve d'Or*, and *Celine Forestier*, always beautiful under glass. In a corner connecting the conservatory with the Rose house, *Climbing Niphetos* was planted four years ago (inside border); this has done so well that it has been introduced from the corridor into the Rose house. It has now extended over 40 feet from the stem, and carries quantities of grand flowers. The back wall of the Rose house is well furnished with *Cassia corymbosa* and *Bougainvillea glabra*, both flowering profusely in their season.

CONSERVATORY AND STOVES.

Passing through the corridor mentioned we enter the conservatory, of which a side view is represented (fig. 120, page 570). This house, 195 feet long by 27 wide and 23 feet high, was erected in 1882. The centre bed is planted with huge specimen *Camellias* in variety, *Acacias*, *Palms*, *Dracenas*, and *Rhododendrons*, many of them reaching the apex of the house. Various other temperate plants clothe the pillars and walls, such as *Tacsonias*, *Coboea scandens variegata*, *Passifloras*, *Rhodochitons*, *Abutilons*, and others. This house is kept gay with flowers at all times when the Court is in residence. It is visited by her Majesty several times during the year.

At present large masses of *Hydrangeas Thomas Hogg* and *hortensis* are very effective, with *Lilium Harrisii*, *Callas* (800 are grown), also *C. Elliottiana*, with many spathes open, very rich in colour; *Pelargoniums*, *Gladioli Colvilli alba*, *Azaleas*, *Ericas*, *Cannas*, *Carnations*, *Cineraria cruenta*, in many shades of colour. Of the latter there are plants 4 to 5 feet high, with heads 3 feet through, making a most charming display. The side stages have depending from them drooping plants of *Asparagus decumbens*, *Isolepis*, *Tradescantias*, and others; and the vista looking through (see figure) from the end of house is further improved by hanging baskets of *Maidenhair Fern*, *Asparagus decumbens*, and *deflexus* alternately at different elevations. In summer these baskets are replaced by others of *Achimenes* in variety.

Joining the conservatory is the plant stove, 75 feet by 21, span-roofed, in two divisions. The first division is filled with a good collection of foliage plants, principally *Anthuriums*, *Alocasias*, *Marantas*, *Dracenas*, and similar plants; all the best varieties of *Nepenthes* and *Dipladenia boliviensis*, *Clerodendrons*, *Gloriosas*, *Allamandas*, *Aristolochia elegans* depend from the roof. Here also is a plant in a tub growing freely of *Nelumbium speciosum nuciferum*. This plant is seldom seen in bloom in this country, but here it expands many of its beautiful large (9 inches in diameter) creamy white flowers, the perfume of which is delicious. The next division is filled with *Crotons* in splendid colour, and include all the best varieties. All the occupants of these houses are taken to Buckingham Palace, Windsor Castle, and elsewhere when required. *Dendrobiums*, chiefly *Wardianum* and *nobile*, are growing freely in this house, some hanging from the roof and some on the side stages.

At the back of this stove—also opening into conservatory—is the Orchid house, 75 feet by 21 feet, in two divisions, this being hip-roofed, the back bed being planted throughout with *Gardenias* and *Stephanotis*, both a mass of flower (fig. 121, page 571). The *Stephanotis* is cut in long garlands, 6 to 9 feet in length. The first division is filled with *Laelia purpurata*, now in splendid bloom, *Cattleyas*, *Cypripediums*, *Oncidiums*, *Lycastes*, *Peristeria elata* (showing nine spikes), and a large number of *Anthuriums Scherzerianum*, *Rothschildianum*, *Andreanum*, with their brilliant spathes now in full beauty. The other division is filled with *Caladiums*, including all the best new forms in fully developed beauty, 300 more started later, coming into use towards the end of June.

Here we noticed a distinct variety of *Crinum* in robust health, and on inquiry were told that it was a variety from Ashantee, discovered on the spot where H.R.H. Prince Henry of Battenberg contracted his fatal illness, and brought to Windsor by Dr. Taylor. It has flowered twice since, and is shown in the illustration 121, page 571.

PALMS AND MUSAS.

At the north end of the conservatory, with which it is connected, stands the new Palm house. This, as will be seen on reference to fig. 122 (page 572), is a fine building of commanding proportions. It was built in the autumn of 1894 by Messrs. Mackenzie & Moncur of Edinburgh. It is 70 feet long, 34 feet wide, and 27 feet high, span-roofed, with an ornamental façade towards the north side of the gardens, from which in the distance it has an imposing effect. The roof is

covered with Cobæa, which depend to within a few feet of the paths in festoons, producing a light and graceful effect. The Cobæa is only temporary, and was planted with a view of hiding the girders as soon as possible, and it in time will give way to more ornamental and useful climbers. On the south side are Allamandas Schotti, nobilis, and Williamsi, and the north side, against rather a high wall, Bambusas nigra and aurea are planted. These come in most useful for decoration, as they can be used in so many ways in large plumes in positions where it is impossible to introduce pot plants, with peculiarly graceful effect.

Conspicuous in this house, and giving a fine tropical effect, are magnificent plants of the Musa paradisaica and sapienta, 25 feet high, although only planted ten months ago. All the best Palms for furnishing purposes are growing luxuriantly, ranging from a small size to giants of 20 feet, and include Kentias, Cocos plumosa and flexuosa, Seaforthias, Phoenix in variety, Thrinax elegans, and Arecas. All these will in a short time be conveyed to Buckingham Palace for the garden party decorations in honour of her Majesty's Diamond Jubilee. A special train is engaged to carry the plants and flowers required on this and similar State occasions.

Leaving the Palm house we come to the Musa house, 80 feet by 20 feet, span-roofed, in two divisions, one planted and now fruited with Musa Cavendishi for dessert. The side stages are filled with Pancratiums, Eucharis, and Hymenocallis. The other division is used for forcing Lilacs, Azaleas, and other shrubs during the winter and spring months, now filled with Gloxinias advancing to bloom. It is pleasing to see that show and decorative Pelargoniums are not, as in many gardens, overlooked. A house 80 feet by 12 is filled with sturdy plants in bloom, and consisting of all the best varieties. Behind this is a house the same size facing north, and is filled with Lilliums Harrisii, longifolium, and speciosum, Arums, Hydrangeas, and white Pelargoniums.

OTHER STRUCTURES.

We have only time to merely glance at the propagating house, Azalea house, pits full of Coelogynes, Cypripedium insigne in quantity; others with Fuchsias, Begonias, Kalosanthes, Poinsettias, variegated Eulalias and Chrysanthemums (2500 grown). Further on is a house containing a fine lot of Caladiums in small pots used for the margins of groups, many hundreds of the dainty argyrites, and the richer C. minus erubescens, besides hosts of Pileas and other dwarf plants for the same purpose. Next comes a fernery 80 feet by 12. This is filled with useful medium sized plants of Adiantums in variety, Pteris, and other decorative kinds. The roof of this house is covered with Clerodendron Thomsoni just coming in bloom. The plants are in pots, and are frequently used for indoor decoration, as they show to advantage when placed in climbing positions round windows and fireplaces.

To give an idea of the cut flowers supplied from the Royal Gardens, it may be stated that 3304 boxes of them were supplied last year, and this does not include wreaths, crosses, bouquets and buttonholes, which are in constant demand.

The foregoing are the main features in the principal houses devoted to plant culture, but by no means exhaust the list. Many of the fruit houses are made to do duty for plants from time to time, as we noticed

in passing that the floor of one Peach house was filled with strong plants of Liliam Krætzleri coming into bloom, another with Francoas, another with Campanulas, and so on, for no space is wasted anywhere that can be turned to account, while none is mis-used by being crowded with useless plants, and it must be said that throughout the department cleanliness and order rule supreme.

HARDY FRUIT.

As might be expected, this is a most important division of the Royal Gardens. It is entrusted to a responsible foreman, with ten men under him, wall fruit occupying the greatest share of attention. The total length of the garden walls are two miles and 200 yards, nearly all occupied with trained trees of one sort or another. Of late years several large old fan-shaped trees that produced little beyond wood and leaves have been gradually removed, and their places occupied by young trees under different forms of training—fan and horizontal, single and double cordon—which bear the best of fruit.

As showing the extent of 12 feet walls occupied by the different kinds of fruit, it may be said that a length of about 200 yards is devoted to Apricots, 750 to Cherries, 500 to Peaches, and 155 to Nectarines, nearly 1000 yards to Plums, and 1100 yards to Pears.

In the open are avenues of standard Apples and Pears, which have evidently been long established, with other avenues, more modern, of pyramids and bushes—not closely restricted, but freely grown, and real fruit producers. A practical point in connection with these trees, and there are many hundreds, is that the summer shoots are not "pinched to four or six leaves, and the resulting growths to one leaf as made," and so on throughout the season. The work would never be done, and besides close pinching is not needed with such trees, for this very good

reason, that all the main branches are so far apart, that there is never any crowding of the foliage. One summer pruning is all the trees have, if that, and the branches are studded with spurs, followed by ropes of fruit when the blossoms escape the frosts of spring. Most of the branches are 2 feet apart, some more, and the heavy crops of fruit keep the growths in subjection. Brief reference may be made to the kinds and varieties of fruit grown in the Royal Gardens appending the actual results.

PEACHES, NECTARINES, AND APRICOTS.

These are protected from spring frost by canvas blinds fixed to the top of the wall, and worked by pulleys. The trees are pictures of health, and the crops full; indeed, they seldom if ever fail.

Peaches are grown to the number of twenty-four varieties, the following succeeding the best, and provide a continuous supply the season through—Alexander, Waterloo, Crimson Gálante, Alexandra Noblesse, Stirling Castle, Grosse Mignonne, Bellegarde, Violette Hâtive, Walburton Admirable, and Barrington. Nectarines.—Early Rivers, Lord Napier, Pineapple, Victoria, and Elruge. Apricots.—Frogmore Early, Moorpark, Shipley's, Hemskerk, and Royal.

CHERRIES.

Cherries, as previously stated, being one of her Majesty's favourite fruits, receive a great deal of attention. Besides the great length of wall accorded the trees a square is devoted to them, having framework

FIG. 110.—PRINCE CONSORT'S MAUSOLEUM AND MEMORIAL TREES (page 552).

fixed of sufficient height to carry the nets above the trees, so that the fruit is protected from birds and gathered without difficulty. The varieties most in favour are Early Rivers, Elton, Bigarreau Jaboulay, Black Tartarian, Governor Wood, Empress Eugénie, May Duke, Late Duke, Archduke, Florence, and Monstrous Bigarreau.

APPLES.

These are grown to the number of 250 varieties in trees of all sizes from maidens to orchard standards. The best *Dessert Apples* are—White Juneating, Irish Peach, and Mr. Gladstone, for July. Williams' Favourite, September Beauty, Red Astrachan, Devonshire Quarrenden, Lady Sudeley, and Gravenstein, for August and September. Ribston Pippin, Cox's Orange Pippin, Mother Apple, Rosemary Russet, King of Tomkin's County, Okera, King of the Pippins, Brownlee's Russet, and Royal Russet, October and November. Duke of Devonshire, Annie Elizabeth, Claygate Pearmain, Adam's Pearmain, Scarlet Nonpareil, and Peck's Pleasant, for December and January. Fearn's Pippin, Baddow Pippin, Reinette de Canada, Lord Burghley, and Court Pendu Plat, from February to May.

The best *Kitchen Apples* are Lord Suffield, Keswick Codlin, Ecklinville, Prince Bismarck, Cox's Pomona, the Queen, and Frogmore Prolific, for August and September. Red Hawthornden, Warner's King, Blenheim Pippin, Peasgood's Nonesuch, Domino, and New Hawthornden, for October and November. Bramley's Seedling, Tower of Glammis, and Betty Geeson, for December. Lord Derby, Gloria Mundi, Northern Greening, Schoolmaster, and Newton Wonder, for January and February. Lady Henniker, Wellington, Sandringham, Dutch Mignonne, and Royal Late Cooking, for the remainder of the season.

PEARS.

Of these there is a great assortment, and the trees of all forms and sizes are in admirable condition. A feature of this garden is provided by the low arched trellises which flank the central walk. They are probably about 4 feet high, and have a span of 5 or 6 feet. All strangers notice them as something of a kind they have not seen before. They were designed probably so that a view could be had of the garden beyond. They are devoted to Pears, and although it might be supposed the blossoms would be much exposed to and injured by frost, we have seen excellent crops of fruit from end to end of the arches, and very convenient for gathering. A glimpse of the Frogmore Pear arches may be obtained in fig. 123, page 573, which shows the broad central walk and the gardener's house in the distance.

Dessert Pears.—The following are found the most suitable, Doyenné d'Ete and Citron des Carmes for July. Jargonelle, Beurré Giffard, and Clapp's Favourite for August. Williams' Bon Chrétien, Beurré d'Amanlis, Madame Treyve, and Colmar d'Été for September. Louise Bonne of Jersey, Fondante d'Automne, and Beurré Hardy for October. Thompson's, Seckle, Doyenné Boussoch, and Marie Louise for November. Comte de Lamy, Bergamotte Esperen, Beurré Bosc, Doyenné de Comice, and General Todleben for December. Winter Nelis, Josephine de Malines, Knight's Monarch, Beurré Sterckmans for January and February. Olivier de Serres, Ne Plus Meuris, Beurré Rance, Doyenné d'Alençon, Bergamotte Esperen, and Easter Beurré for the remainder of the season. *Kitchen Pears.*—Vicar of Winkfield and Uvedale's St. Germain.

PLUMS.

Plums are under the average this year in cropping, having suffered from spring frost. They are grown in forty varieties, the best of which are as follows: *Dessert.*—Early Favourite and The Czar for July. Green Gage, De Montfort, and Denniston's Superb for August. Angelina Burdett, Cloth of Gold, Jefferson, Kirke's and Transparent for September. Blue Impératrice and Ickworth Impératrice for October. The best *Kitchen Plums* are The Sultan, Orleans, Prince Engelbert, Red Magnum Bonum, White Magnum Bonum, Pond's Seedling, Victoria, Diamond, and Autumn Compôte.

Nearly 3000 young fruit trees of one sort or another have been planted during the past five years.

STRAWBERRIES.

Strawberries are grown to the extent of 2 acres. Most of the new varieties are included in the collection, which number fifty named sorts. Several new ones raised by Mr. Thomas within the last few years are being carefully tested on a border set apart for the purpose, some of which promise to occupy an important place in the list of first-class Strawberries. Sir Trevor produces ripe fruit several days in advance of any other, Laxton's No. 1 previous to this being looked upon as the earliest Strawberry in cultivation. Cold nights during the early part of

May did considerable damage to the crops in general, but at Windsor a thick layer of straw was placed between the rows early, and allowed to remain loose. This can be quickly thrown over the plants when frost threatens, to protect the early blooms from injury. When no longer required for that purpose it is levelled down as a bed for the fruit to rest on. The crop looked very promising indeed.

The varieties found the most useful on the heavy soil are as follows, placed in order of their ripening:—Laxton's No. 1, poor flavour; Noble, large but insipid; Royal Sovereign, a few days later, with good brisk flavour, and well worthy of the name it bears. La Grosse Sucrée comes next, and does well. Sir Joseph Paxton, Sir Charles Napier, Countess, President, and Leader closely following, the last named being one of the best cropping Strawberries in cultivation. For late supply Waterloo is a great favourite. Other varieties for this purpose are Commander, Latest of All, and Frogmore Late Pine. This season is quite a fortnight later than last, when the first punnet of Laxton's No. 1 was gathered on May 18th.

The best hint conveyed here, and which ought not to be lost sight of, is the "strawing" the beds. This is not usually done till the fruit is commencing to ripen, and injury is often done in packing it under the trusses. By piling it loosely between the rows just before the flowers open the flowers are sheltered and may be easily protected on a frosty night by scattering it over them. The litter then only needs pressing down to keep the fruit clean. Two purposes are thus served, and much less time occupied than by the old method of late application.

SOME RESULTS IN THE ROYAL GARDENS.

That fruit is produced in large quantities will be seen by the following figures, taken from the garden book for 1896:—

Apples,	2050 dozen and 450 bushels.
Apricots,	420 "
Cherries,	1220 lbs.
Plums,	390 dozen and 500 quarts.
Green Gage,	74 " and 40 quarts.
Pears,	2021 " and 22 pecks.
Peaches,	400 "
Nectarines,	130 "
Gooseberries,	1550 lbs. and 262 quarts.
Currants—Black,	640 lbs.; Red, 1406 lbs.; White, 173 lbs.
Raspberries,	656 lbs.
Strawberries,	2000 lbs.

These figures relate to fruit grown in the open gardens. The "dozens" indicate selected dessert fruits; the bushels, pecks, and quarts kitchen fruit; pounds, the supply for both purposes. It is a goodly total, even for a Royal household.

Black Currants have suffered from frost, and the crop will be under the average.

VEGETABLES.

Having previously given the dimensions of this immense garden, and indicated the nature of the soil, the system of cultivation and of cropping may be briefly referred to, and the great provision made and supplies obtained concisely recorded.

As regards the system of cultivation and rotation of crops, the following is as closely adhered to as possible. A few acres are trenched from 2½ to 3 feet deep, and heavily manured every year. This area is cropped the first year with Peas, followed by winter salads, and the following year usually occupied with Brussels Sprouts. (The best Cabbage Lettuce for winter and spring work is still the old Stanstead White, and the more open, exposed, and dry the aspect is the better it is found to suit the requirements of the plants in winter). For economy of management this land is not again dug with the spade for three or four years, but the horse and the plough are brought into requisition instead to expedite work, with a rotary cultivator with strong slightly curved prongs to break the clods. Another system adopted is to manure heavily in beds for Celery, the next season cropped with summer Onions, autumn planted Cabbages following, then early Potatoes, Strawberries, and spring Broccoli in rotation.

Many thousands of roots and crowns of Asparagus being required annually for forcing purposes alone, new beds are formed and planted extensively every year. The site for one of these beds is always open as a receptacle for garden refuse as a foundation, and turning this refuse at the same time to good purpose by converting what is often wasted into good and fertile soil. On the top of this refuse is spread a layer of good decayed manure, to be covered with soil, that was thrown out in making the wide trench, before the beds are planted. By following the system success is always attained. It is a simple and excellent method, worthy of more general adoption.

In general summer culture importance is wisely attached to the timely and frequent use of the hoe. It was found that the Sproughton hoe is a favourite with the men, who seemed to enjoy the work, as no doubt they did, of skimming it through the surface between rows of young Carrots and other crops, deftly turning it up as they went along to pick the weeds from among the plants with the pointed prong. "Do you like the new hoe?" was asked of one of the workers. He seemed astonished at what was perhaps to him a stupid question, as he replied, "Like it, sir? I should think we do. It's a fine thing, sir, I can tell you;" and on he went, skimming and pronging, as happy as a prince.

Little surprise need be entertained at the enormous quantities of produce required from this garden, as when her Majesty is residing at Windsor Castle, upwards of 300 (of course including servants) dine every day. The number is not so large at Balmoral and Osborne, but supplies are sent from Frogmore daily.

Of Asparagus, previously mentioned, three acres are grown. Cutting begins (in frames) in November, and is continued, forced and naturally grown, for about seven months.

Early Potatoes are grown on beds of leaves, in heated pits, and on borders sheltered by the fruit walls; also about 70 tons of late sorts are grown and pitted for winter and spring use. Such old varieties as Dunbar, Regent, and Fortyfold are retained for their superior quality.

Celery for early use is grown in the ordinary way, in single rows, but the main crop is grown in excavated beds 6 feet wide, and planted across in rows. No less than 40,000 plants are put out on this system.

Onions raised in the autumn are planted out 1 foot apart for summer use, and in favourable seasons 500 bushels, raised from spring sowing in the ordinary way, are stored for winter.

Nearly 30,000 Lettuces were supplied last year, as many as 120 dozens, on special occasions, having been used in one day. Salad is an important item, and in dry seasons it is difficult to maintain a good and regular supply. Except for the early crops the seed is sown in drills and the plants thinned, not transplanted, as when undisturbed they are less liable to "bolt."

The main crop of Peas, in rows 110 yards long, would extend some five miles, and some of the reliable and well-tried sorts are sown by the bushel.

For early crops (cutting in June) 2500 Cauliflowers are potted in large 60's and wintered in cold pits; some 40,000 others in variety being planted in succession; 12,000 Brussels Sprouts have recently been planted out, 30,000 Savoy, the same number of Cabbages, 10,000 Scotch Kale, 25,000 Endive, and Broccoli of sorts on the same large scale.

Horseradish is frequently seen in gardens in some out-of-the-way corner, and perhaps only required at Christmas; 5000 sticks are required here annually; 20,000 Seakale crowns are grown yearly, and lifted for forcing; 600 lbs. of Tomatoes are required for bottling (sauce) alone every autumn, besides the daily supply, nearly all the year around; and so we might go on, but it is not necessary, the facts adduced, for facts they are, sufficiently show the important part the garden plays in supplying the essentials of health to the homes of the Queen.

This could not be done, in the way it is, in the absence of closely studied economy—making the utmost use of all resources, and reducing waste to a minimum. It could not be done without knowledge on a variety of subjects, sound judgment, clear foresight, constant watchfulness, cultural skill, unity in effort, and devotion to duty; and it is just because all these essentials to success are present that the great gardens of the Queen are so creditable to all who share in making them so productive and maintaining them so well.

WINDSOR GREAT PARK.

As previously indicated, Windsor Castle and Frogmore are within the Home Park, but there are gardens or features of interest beyond—namely, in the Great Park—an area of woodland and forest scenes of some 20,000 acres. This is reached from what is known as the "Long Walk," a term which is in no sense expressive of the imposing dignity of this glorious avenue of English Elms. A delightful drive of some two or three miles, affording a glance at Prince Albert's Plantation on the left, past noble Beeches and through picturesque groves, we arrive in a large opening near a pretty church, opposite which is a cosy mansion, and there we make a call.

THE ROYAL LODGE.

Such is the name of this charming sequestered home, recently, we understand, placed by her Majesty at the disposal of Lady Churchill. A long and lofty conservatory is the connecting link of the mansion with the park. It is really an avenue of ancient Camellias, with large tree-like stems, but the shrubs, pruned to form tall hedges of rich foliage, and, in season, studded with blooms. These Camellias must have been planted at the time of the first introduction of some of the varieties. With them is also probably one of the oldest "trees" in the kingdom, with woody stems 12 to 15 inches in circumference, of the purple Cape Milkwort, *Polygala oppositifolia* *Dalmatiana*. An old tree of the Silver Wattle, *Acacia dealbata*, and the trumpet-shaped flowers arching over the path, of *Brugmansia*, or *Datura sanguinea*, the growths issuing from a thick rugged stem, are noticeable in the collection.

The pleasure grounds are also of the old world order—huge masses of Rhododendrons, wide spreading bushes or low trees of American Azaleas, with *Kalmias* of such stature as are rarely seen. The Sikkim Rhododendron *Falconeri* seems also happy in the enclosure. More modern are the Rose beds of Crimson Rambler and others, managed on the long rod system, the strong summer growths being trained almost horizontally about 18 inches from the ground to produce, as they do, sheets of flowers. A quiet, secluded, charming place of rest is Royal

Lodge, but we must leave it for a glance at something not less interesting in its way.

CUMBERLAND LODGE AND ITS VINE.

After a few minutes' drive we reached the vinery. With the Lodge and its gardens we have nothing to do. They belong to Prince Christian, who has his own excellent gardener in Mr. Greyer. But it may be said that the term "Lodge," as usually accepted, does not adequately represent the huge, plain, massive building to which it is here applied. The Vine her Majesty retains as her own, and hence it comes under the control of Mr. Thomas, who watches it with solicitude, and is looked to for guidance in routine by its attendant, who is anxious that nothing shall be left undone that can minister to its health. It is worthy of all the thought and care and skill that is bestowed upon it, and for which it is this season making a particularly gratifying response. "Breaking better than ever," and "showing capitally," are cheering observations. This is, in part, it may be expected, the result of the longest possible winter's rest, and in part, the effect of removing weakly laterals, and encouraging the strong to extend wherever there is room for leaf expansion. Sound policy this, without a doubt; and, it may be said, the only means by which the old Vine can be invigorated, beyond what can be done for its roots. The huge Vine is planted in the centre of the

FIG. 111.—DUCHESS OF KENT'S MAUSOLEUM (page 552).

house, and the roots extend to no one knows exactly where; but endeavour is being made to induce a new surface layer from the stem, and not without success; and just as these increase and multiply there, and young rod extension is encouraged, so will the grand old Vine be benefited, its vigour increased, and its life prolonged.

Great as is the extension of this remarkable Vine, covering as it does 3450 square feet of roof space, it is all the same restricted, and has been for some years. How far it would extend if additional space could be afforded it is difficult to say, but as past extensions have led to greater invigoration, similar results must almost of necessity follow if it should happen in the course of time that means could be devised for giving it further liberty. The Grapes, about 2000 bunches, produced by this splendid Vine are of the first quality, and we suspect they will be finer than usual this year, which is something to say for a centenarian.

personal present to her Majesty by the contributors to the fund. It is reached by a curving drive, flanked by recently planted belts of Rhododendrons.

VIRGINIA WATER.

No portion of the Great Park (to which it may be said the public has access) is more beautiful than that known as Virginia Water. "Menzies," late surveyor of the Park, mentions in his history of it that the name is derived from a brook that originally drained this portion of the Park, and this brook was named "Virginia," after Queen Elizabeth, the Virgin Queen. The extent of the water is now 300 acres, which takes bold sweeps between richly wooded banks, rising in places to something like mountains of foliage, of Beech, Birch, Firs, and Willows, not in indiscriminate mixture, but evidently in accordance with well-considered design.

FIG. 112.—BUCKINGHAM PALACE (page 562).

It should be added, that almost adjoining the vinery is one of the schools supported by the Queen for the education of the children of the many workmen who are engaged in the Great Park; and further, that ample ground is attached for the teaching of useful gardening to the scholars, a practice that has been in operation here for many years.

THE EQUESTRIAN STATUE OF THE PRINCE CONSORT.

Proceeding from Cumberland Lodge southwards we emerge from the trees into a large opening, known as "Smith's Plain." Some distance to the right stands an equestrian statue of the late Prince Consort, looking towards Windsor. Ten years ago many thousands of pounds were collected by the women of the United Kingdom as a Jubilee gift to the Queen. This her Majesty devoted to the establishment of the Royal Nurses' Institution, with the gratifying result that already hundreds of trained nurses are available for ministering to the wants of the sick and destitute poor; and as the funds increase so will these real sisters of mercy, to remind of the tender heartedness of the Queen, of whose application of the gift this statue is a substantial memorial—a

Hughes, in his recent "History of Windsor Forest" * says: The laying out of Virginia Water was commenced in 1746 by the Duke of Cumberland, who was appointed chief ranger in that year. He installed Thomas Sandby, Esq., as deputy ranger, this gentleman aiding him in the works of improvement. The first Virginia Water was apparently completed between 1750-52, for a plate bearing the date 1753 shows a lake of considerable size, with the Belvidere in the distance. This was taken from a picture by Paul Sandby, Esq., an artist, brother to Thomas Sandby, who aided the Duke in designing the Waters. About this time the Duke left England and was engaged in wars in Hanover, returning in 1757, when, being in disfavour with the King (George II.), he threw up his military appointments and retired to Windsor, where he found congenial occupation in further laying out and planting the hill-slopes of the Virginia river. The *Annual Register* of 1768, speaking of a deluge of rain that fell in that year says: "The late Duke of Cumberland's fine waterworks in Windsor Forest were entirely destroyed."

* Ballantyne, Hanson & Co., 1890.

The lake was restored by the second Duke of Cumberland, under the direction of Mr. John Pitt (Royal Surveyor of Woods), but some time elapsed before its completion. "Indeed, it seems not to have been finished until 1790, at least in its present form."

There is a tradition that French prisoners of war were employed in this gigantic work, but of this there does not seem to be any public record.

THE ROYAL FISHING PAVILION.

As an occasional resort of the Queen, this surely is one of the most delightful. The Swiss chalet-like building is situated on the margin of the lake, overlooking its greatest area. It is reached by a short flight of steps from the garden, and we can pass right round the building under the verandah, the wooden platform and balustrades extending over the water.

The garden is circular in form, completely enclosed by trees and

In the distance is a bright knoll, a sort of spur raised and planted with the Golden Cypress, choice Rhododendrons, and Mollis Azaleas. The drive curves between the Pines with their undergrowth of bracken to the Pavilion. It is surrounded by broad gravel promenades bounded by raised banks, which have recently been transformed into narrow terraces sloping to the Pavilion, and planted with *Erica carnea*. Nothing could be more appropriate, for they will be beautiful in the spring and agreeable at all times.

The site of the Pavilion is high above the surrounding ground. On the north and west we looked down on masses of Rhododendrons, and over them across a wide stretch of country, including Laffans Plain; on the right, as if in a dell, and completely hidden by tall Hollies, are the kitchens and other domestic appurtenances of the Pavilion, which is entered from them by a subterranean passage.

In the pretty gardens of an official is a naturally grown standard

FIG. 113.—BALMORAL CASTLE (page 565).

evergreens, so closely grown as to be of hedge-like density. There is an encircling path and a central lawn, this containing a modest fountain and a noble Cedar, with inviting seats under its far-spreading branches. Near the margin of the lawn is a series of flower beds, which are kept gay in spring and summer. In order faultless, a more charming spot than this pavilion garden it would be hard to find. At the end of the "Ascot week" H.R.H. the Prince of Wales and other members of the Royal Family are said to frequently spend an evening on the lake—beautiful Virginia Water. Thus end our brief references to some of the interesting and attractive features of Windsor Great Park, and now we pass from Royal Windsor.

ROYAL PAVILION, ALDERSHOT.

In what may be termed the wilds of Surrey about 14,000 acres of land are devoted to army purposes, and near the busy town of Aldershot her Majesty, as head of the Army, has her military home. At the entrance to the grounds near the barracks is a large expanse of gravel, overlooked by official residences and guard rooms, recently covered with creepers and Roses. The general effect has also been enhanced by the planting of trees, the tender green of the Limes contrasting well with the forest of Pines beyond.

Peach tree, not attached to a wall, which last summer ripened fifteen dozens of excellent fruits of the Royal George type; and young standard Apricot trees have been planted, in the hope that they will bear and ripen crops of fruit in due time, as no doubt they will when the summers are bright, for they vary even in salubrious Surrey.

But we must leave this Royal enclosure, of perhaps nearly a hundred acres, with its forest-like surroundings and quiet solitude. Quiet as it was then, but soon will be heard the war trumpets and the drums, the rattle of musketry and the booming of guns, when the troops are called out for review, and to fight a mimic battle on Laffans Plain.

HAMPTON COURT.

Cardinal Wolsey surrendered Hampton Court to the Crown in 1525, and with the exception of a few years in the sixteenth century it has remained a Royal residence to this day. It is, by the grace of her Majesty, the home of many families, and has the population of a good-sized village. As is well known, the grounds and gardens are open to the public, save a very small portion, including the orangery and famous Vine, this portion being retained by the Queen, but the public have free access to the vinery under certain regulations, and it is recorded that 6000 visitors have availed themselves of the privilege in one day.

The chief object of our visit was the Vine. Some few years had elapsed since the previous inspection by the writer, and it was thought then with regret that it betrayed symptoms of weakness, as undoubtedly it did, and when an ancient Vine like this takes a wrong turn it is no easy task to effect any material invigoration. It was with some surprise then and much gratification that the Vine was found to be in unmistakeably better condition than it was several years ago. The bearing wood is stronger, the leaves larger, and the bunches finer than was the case then, and the whole Vine, save its massive stem, has a distinctly younger appearance.

In an attractive little souvenir of the old Vine, dated August, 1894, but *minus* the name of the author, though we suspect his initials are "O. T.," it is stated the Vine was planted in the reign of his Majesty King George III., and it is therefore 129 years old. The girth of the stem, when measured for the purpose of the souvenir, was $3\frac{1}{2}$ feet, the branches covering an area of 2200 feet, much less, it will be seen, than the Cumberland Lodge Vine, which it is supposed is an extension of this at Hampton Court, as furnishing the cutting from which the greater giant was raised.

The Vine is said to have produced (by dangerous overcropping in the past) 80,000 lbs. of Grapes, and surely then, having done so much and for so long, it ought not to be overpressed in its old age. It will not be.

The old Vine is cherished by its Royal owner, the chief gardener, his trusty assistant, and by the public. The attendant thinks it has a long and fruitful career before it, because the laterals now "bulb up" so well near the base—an observation not often heard, but all the same, with something in it.

We should like to say more about Hampton Court and the Queen's 300-years-old Orange trees, also to explode a popular fallacy, for the circulation of which Mr. Graham is largely responsible through his "Guide"—namely, that the interesting old Dutch gardens were laid out by Loudon and Wise. Mr. Wise was taken as a partner in the Brompton Nursery in 1694, while Mr. Loudon was not born till 1782. The gardens were laid out by Loudon and Wise, who were partners, and both of them Royal gardeners; but the allotted space is filled, and the subject cannot be pursued.

THE STAFF OF THE ROYAL GARDENS.

For the management of all the foregoing gardens and pleasure grounds of the Queen—the trees, the drives, and the supplies of all kinds—Mr. Owen Thomas (fig. 124, page 574) is responsible, his staff numbering from 125 to 130 men. For the purpose of effective working there are departmental foremen, each having his staff of men, who are responsible to the head gardener, who speaks in high terms of the ability of his experienced coadjutors.

The kitchen garden at Frogmore is in charge of Mr. Chas. Marr, who has held the position for upwards of fifty years.

The plant department is in the charge of Mr. T. Edwards, who has held the position for upwards of twenty-four years, and who also assists Mr. Thomas with office work.

The fruit under glass is in the charge of Mr. J. Dunn, who counts about fourteen years' service.

Hardy fruit is under Mr. J. Brown, also about fourteen years' service.

Frogmore House Grounds, until recently, were under Mr. J. Cruickshank, who had worked in the Royal Gardens for fifty years, and since his death have been in the charge of Mr. Barker.

The Castle gardens and slopes are in the charge of Mr. J. Chennell, who has close on forty years' service to his credit.

The roads and plantations are under Mr. J. Hampton, of about forty-five years' service.

The Royal Lodge gardens have been in the charge of Mr. J. Green for about four years; Hampton Court private garden and the old Vine under Mr. J. Jack for fourteen years; and the Royal Pavilion, Aldershot, under Mr. J. Carruthers for thirteen years.

All the foremen have excellent cottages and gardens round them, and all live within easy distance of their work. If through long years of service any of the men are incapacitated, a provision is provided for them for the rest of their lives. Their wages are not stopped through any temporary illness, and altogether every consideration is shown to them.

All constructive work and repairs in the Royal Gardens are carried out by her Majesty's Office of Works, including all boilers, of which there are twenty-six.

In a large establishment like this, with the various departments in the Castle to supply, it is evident that business must be conducted in a systematic manner, first to provide and then to insure the safe and

punctual delivery of goods, and to avoid confusion. Every article that leaves the garden, whether in the form of 2 or 3 tons of Potatoes, a bunch of herbs, a bouquet, or anything else, is entered in a day book, and charged at market prices, a list showing quantity and weight being sent to the heads of departments concerned every day; also a similar list, giving the daily total supplied, to the Master of the Queen's Household.

A monthly statement is sent to the Board of Green Cloth, also quarterly returns and balance-sheet, showing every item bought for the different departments under the head gardener's superintendence, and the value of produce supplied for the corresponding period. The Royal Gardens, which are in splendid condition throughout, are in the department of the Lord Steward of her Majesty's Household.

The illustrations of subjects represented in the Royal Gardens of Windsor and Frogmore are prepared from photographs by Messrs. Russell & Sons, photographers to the Queen, Windsor and London.

BUCKINGHAM PALACE.

THE traveller along Buckingham Palace Road or Grosvenor Place, though interested and curious regarding the London residence of her Majesty the Queen, would not conceive that beyond those high walls was one of the most charming retreats in or near London. The popular idea is that the grounds or gardens are comparatively small, but this impression is quickly dispelled when the inside is reached. Then the size seems to grow very appreciably, increasing as the walks between the trees, over the bridges across the lakes, and through the dells are traversed. There are acres of water, acres of lawns, and acres of shrubberies, and so skilfully has the planning been carried out that the gardens appear considerably more extensive than is actually the case. Still we are reminded that we are in London by the rumble or the hum of the great tide of traffic that seems ever flowing between Hyde Park Corner and Victoria Station.

Historically Buckingham Palace is very interesting, and has seen many changes. Originally the site was a Mulberry garden, but in 1703 old Buckingham House was erected by John Sheffield, Duke of Buckingham. A remnant of the Mulberry garden remains in one solitary tree standing near the house of Mr. J. R. Stirling, the gardener who acted as our guide. In 1761 the house was purchased by George III., and it was not until 1825 that the work of demolition was commenced to make room for the present Palace on the same site. In July of 1837 the new erection was finished, and occupied by the Queen. It was from the exterior of this Palace that the Marble Arch, so familiar to most people who have visited London, was taken down for re-erection in its present position at the Cumberland Gate of Hyde Park, this work being done in 1851, two years prior to some extensive alterations that were made in the structure.

At the outset it must be understood that the pleasure grounds are mainly artificial; the ornamental water has been formed, huge mounds have been thrown up, and cool, secluded walks wind beneath the handsome trees. Referring primarily to the lake, which occupies an area equal to 8 acres, we see with what consummate skill the planting has been done so as to give the visitor fresh views across the water, with glimpses of the Palace at intervals between the trees. It is a noble piece of work, executed under the direction of some master mind whose appreciation of natural beauty was of the very keenest.

At the head of the water, which is really a series of lakes, stands an enormous mound built up, it is but natural to surmise, with the soil taken out from the waterway. Its steeply sloping sides are clothed with trees and shrubs, and it is surmounted by a handsome pavilion. It serves a twofold purpose—namely, to screen from the view the Royal Mews, and to command from its summit the whole panorama of the gardens and the Palace. We worked our way up by gravel paths, with their verges of grass, and richly were we rewarded by the arboricultural picture spread beneath us. The windings of the lake were clearly seen, on whose placid waters ducks and other waterfowl were floating lazily in the sun.

It was then, too, that we realised to the full how splendidly the grounds are wooded, and with what a variety of trees. Interesting and instructive—the former as showing the extent of the demesne, and the latter as illustrative of what trees thrive best amidst the smoke of our vast metropolis. There was no difficulty in arriving at a conclusion as to the best tree of all, for the stately specimens on all hands proclaimed the Plane to be the tree of trees. Dozens, nay, hundreds of kinds have been planted at various times; but of all those mentioned have done the best, though Thorns are little inferior, and Elms are very fine.

Of flowering trees and shrubs Laburnums are splendid, as are Guelde Roses, Rhododendrons, Azaleas, Weigelas, and Lilacs. Each of these flowers with freedom, the first named being particularly effective at the time this visit was made. Notable also is a beautifully coloured Copper Beech, conspicuous more for its form than for its size. It is growing to one side, due in all probability to the graft having been taken from a side branch instead of a leader, and obeying some natural law in growing outwards, as it would have done had it remained upon its parent.

Trees as a rule, except the Plane, do not retain their freshness long after midsummer in the London atmosphere. An instance of its effect may be cited in a long Ivy-covered brick wall, to which the growths will not—cannot—cling, but all of them have to be secured with nails and shreds.

As is well known, her Majesty does not utilise Buckingham Palace

In its ordinary bedding plants, such as Zonal Pelargoniums, Lobelias, Calceolarias, and others are grown, and as this enclosure is reached by winding paths, it comes with many charms. The plants inserted were splendidly healthy, and should give a good display.

On the left hand side of our illustration, but obscured from view by the tree, stands an old conservatory of considerable dimensions, in which Zonal Pelargoniums are luxuriating. The structure, which is very lofty, is supported by columns, up which the plants mentioned are trained; and very beautiful they looked, with their brilliant flowers. No other plants could be induced to grow so satisfactorily here. On the side stages are similar plants, while the centre is occupied with stately Palms, in splendid health and condition. Truly are the grounds of Buckingham Palace charming—an ornament to London, and a credit to Mr. Stirling, in their cleanliness and the health of the occupants.

FIG. 114.—THE QUEEN'S TEA ROOMS AND EVERGREEN OAKS (page 552).

as a residence to any material extent. Yet it is of great value, and in much demand for the holding of the Royal garden parties, to which purpose its grounds are so admirably adapted. On the extensive lawns before the noble building large marquees are erected, and those honoured by invitations can wander at will beneath the trees and by the water. Look for a moment at the photographic illustration (fig. 112, page 560) by Mr. H. N. King, Royal photographer, Avenue Road, Shepherd's Bush, W. This will convey an idea of the garden-front of the mansion, and it is on the lawns in the immediate foreground that the marquees above alluded to are placed. The grass has a gentle slope to the water, shown in the picture, and surely no better place could be wished for or found in London for a similar purpose. The mansion is imposing in its air of substantiality, and the carving on the facade is very fine.

Gardening, as the word is usually interpreted, is not very extensively carried out here—indeed it is really limited. There are many borders containing old-fashioned flowers, but the one geometrical garden is small.

OSBORNE HOUSE.

Fair is the Isle of Wight, varied are its pastoral pictures, and here far from the busy haunts of men is the southern home of our Queen. We have spoken of Windsor Castle with its multitudinous departments, and of Buckingham Palace, both of which are Crown residences where life runs on at high pressure. Now we would transport the reader to Osborne House, one of the two private domains of the Queen, and the one about which is enwrapped many sacred memories of the late Prince Consort. There are no evidences of modernity here save where they tend to comfort. On the contrary, the seclusion and peacefulness form perhaps its greatest charm. True examples of English enterprise may be seen from the seashore in the mighty ships that pass to and from Southampton Water, or which may be observed ploughing their way towards the busy town of Portsmouth.

Though it is our intention to regard the Osborne demesne horticulturally rather than otherwise, it may be well to state when her

Majesty first became possessed of it and what has been done to improve it since that time. The estate was purchased so far back as 1845, and the improvements were at once commenced. The chief of these was the rebuilding of the mansion, which is now a very handsome structure. An excellent idea of the style of architecture is afforded by the photographic illustration (fig. 126, page 576), which shows the sea front. "Imposing and substantial," is the verdict of most of those who look on it. Within, the style is one that tends greatly towards comfort, for here, as at Balmoral, the Queen seeks repose, and it is doubtless to these two resting-places that must be ascribed the remarkably vigorous retention of the faculties for which her Majesty is renowned. To us it seems no better place of repose could be found than Osborne House, with its delightful situation and magnificent surroundings.

Beautiful indeed are the grounds, with their miles of sea-board. The character of the land is very undulating, and it is surprising to see how almost all kinds of trees and shrubs luxuriate. Thousands have been planted, and probably hundreds of them have a history of intense interest. As progress is made through the estate, trees, mainly coniferous, are constantly being seen, whose labels tell by whom they have been planted, and when. Almost, if not quite, all the members of our Royal Family have added to this arboricultural collection, while scions of other Royal houses have also done their share. The lover of trees would find much to interest him in the specimens at Osborne, for well as the majority have grown, some few have barely survived, while others have succumbed. We could not attempt here to give particulars of the many trees—space could not possibly be found; but it may be said that the *Thuias*, *Retinosporas*, *Piceas*, *Librocedrus*, and *Abies* amongst the Conifers, with the Austrian Pines and Cornish Elms, which form the magnificent avenue leading from the East Cowes entrance (fig. 125, page 575) to the mansion, are very conspicuous. Myrtles, too, as is well known, are numerous and fine, and to each there is attached some history, as also is there to some of the Cedars of Lebanon. Besides those already mentioned, *Rhododendrons*, *Paulownias*,

actually within the range of vision. On the terrace bedding is largely carried out, but nothing in the slightest degree out of the common is attempted. It is her Majesty's desire that no radical change shall be made, so that each year sees the Zonal Pelargoniums, the Lobelias, the Calceolarias, and others with seasonable regularity. To all intents and purposes this is the only flower garden on the place, though each of the several entrance lodges have flowers of a similar character planted about them by Mr. George Nobbs, the gardener.

Now we pass down from the terrace by the broad stone steps and along "the walk to the sea." It is a delightful road to travel by, for interesting trees are constantly seen, as well as charming views through the woods, in which wild flowers are at home. It is a considerable distance ere the shore is actually reached, but it is grand when once there. The rising ground on the mainland, about seven miles distant, acted as an admirable foil to the ship making its way to Southampton. How different this water was on the night of June 22nd from its appearance on a day in May will readily be imagined.

Passing along a paved promenade, against the walls of which the water was continuously lapping, we quickly arrive at one of the extremities of the estate, and through narrow paths and broad drives between the trees reach another point from that at which we entered. On our way across the grass by the cattle lazily browsing we note a handsome pavilion that was presented to her Majesty by Messrs. Sutton and Sons only a short time ago. The style in which it has been erected makes it quite an ornament to the landscape, the design being light and graceful with combined evidence of strength. Still pressing onward to our goal—the garden—we eventually found ourselves amid signs of activity in preparations for the bedding.

If the bedding arrangements to which Mr. Nobbs has to give his attention were confined to the terrace garden they would not be very arduous. Such, however, is by no means the case, for the flower gardens of Kent House, Victoria Cottage, which is in the occupation of Mr. George Woodford, by whom the three photographs were taken,

Albert Cottage, Osborne Cottage, Swiss Cottage, May Cottage, Arthur Cottage, the Queen's Almshouses, and the eight entrance lodges, each have to have the most careful attention, so that the bedding becomes an item that must be reckoned. For the purpose under notice, then, 60,000 plants are required yearly, and those that were about to be planted showed abundant evidence of excellent culture. Fortunately the number of frames for their reception is large, or the difficulty of raising and maintaining in good health such a quantity would be well-nigh impossible. They looked sturdy, strong and clean, stock of that

FIG. 115.—KITCHEN GARDEN TERRACE (page 554).

Catalpas, Arbutus, Hollies, and *Eucalyptus globulus* are abundant, not to mention the smaller flowering and foliage shrubs that are met with on every hand. With such surroundings as these, such family ties, can one wonder at the Queen's attachment to Osborne House?

Let us return for a moment to the illustration of the house to call attention to the terrace therein depicted, and shown also in fig. 127, p. 577. From a central position on this a magnificent view is commanded of the park, with occasional glimpses through vistas in the trees to the Solent, and beyond, when the atmosphere is clear, to the Hampshire coast, with Portsmouth on the right, and Southampton on the left, but neither

nature which everyone expects much from before the season is over. Neither does the work finish with the planting, for at each centre everything must be scrupulously neat and clean, so that it is no exaggeration to say the bedding as a whole entails much thought and labour to cope with it satisfactorily.

The gardens—and by this we mean the vegetable, fruit, and glass departments—are very limited in extent, though improvements are now being gradually made therein. The vegetables and hardy fruits are cultivated in one small enclosed garden; but limited as it is, really good work is done. The trees, mostly bush trained, were, at the time of this visit,

in capital condition—clean as regards insect pests and fungoid visitations, and built up of sound, healthy wood. Vegetables were scarce; but all the quarters were free from weeds, and preparations for their occupation were proceeding apace. Under glass the collection of plants is a very general one, comprising Orchids in small numbers, several handsome Ferns and Palms, with the several other kinds usually found in a collection of this nature. Mushrooms are splendidly grown in one of the outhouses, and the garden bears in its condition the impress of careful and painstaking attention to the details natural to it.

Brief as is this reference to Osborne House, it must suffice for the time being. Yet mention ought to be made of the surroundings that are, as it were, a part of the estate. Whippingham village and church, for example, are well worthy of more than the passing glance which alone can be given them. No place is more intimately associated with the private life of her Majesty and the late Prince Albert than St. Michaels, Whippingham, and all visitors to the "Garden Isle" ought to go there. In drawing to a conclusion we would acknowledge our indebtedness to Mr. G. Woodford for supplying the excellent photographs, and to Mr. G. Nobbs for his trouble in giving all the information in his power, and showing everything that he thought would be of interest.

BALMORAL CASTLE.

PROUD as we of the British race are of the record of her Majesty's wonderful reign, we look with especial pride upon the domestic virtues by which it is adorned. We feel that the Royal palaces are not only State residences but homes in the true sense of the word, made so by the character and example of our Sovereign herself. None of these reveals this more than Balmoral, where, surrounded by the magnificent scenery of Deeside, the Queen finds rest. Only a few days before her Majesty's arrival for a brief stay previous to undergoing the fatigues and trials of the Jubilee celebrations, it was the privilege of the writer to see this Highland home, of which an illustration is given on page 561.

The visit was an enjoyable one, made more so by the courtesy of Mr. James Forbes, who has recently been appointed her Majesty's Commissioner, and Mr. John M. Troup, who fills so ably the responsible position of gardener at Balmoral. Mrs. Troup also showed equal kindness, while Mrs. Musson, the housekeeper at the Castle, gave some time at a busy season to escort me through the public rooms.

The drive from Ballater on that bright but sharp morning in May was a delightful one. The air was pure and clear; the sun lit up the mountains, the river, and the trees. Lochnagar in the distance stands high above all with its snowy mantle; while the Birches, the glory of the Highland rivers and glens, were exquisite with their delicately beautiful and quivering leaves.

Those who might expect to find Balmoral gardens a copy in miniature of those at Windsor would find themselves disappointed. This is not desired. Balmoral is one of those places where elaborate gardening would appear incongruous. With the magnificent scenery around, Nature seems to claim supremacy over Art. The climate, moreover, places a limit to the practice of gardening, as if to compel acquiescence in this plan of Nature.

Dahlias will not bloom, even if planted out when some height; and Clematis Jackmanni has to be grown under glass. The thermometer fell to 49½° of frost two winters ago, and occasionally 10° of frost is experienced in June. Yet it is not to be supposed that the gardens are poor and unattractive. Not so; but the system is adapted to the desires of the Royal Family, and the work done is the highest of its

kind. Mr. Troup has had long experience of gardening in the north, and it is amply evident that, spurred by devotion to the Queen it is his privilege to serve, no one could carry out more skilfully the work entrusted to him.

The requirements of the household in the way of fruit and vegetables are principally met from Windsor; but of the former some Gooseberries, Raspberries, and Strawberries are grown. The Strawberries are Myatt's, Elton Pine, Aberdeen Favourite, and Latest of All. The last is being grown for the first time, but it is expected that it will prove satisfactory here. These Strawberries are for late use, and are often obtained in perfection until well into September. The glass houses are six in number, none very large, and mostly three-quarter spans, facing the south. Such houses are more suitable for the severity of the climate than any other, and they are filled with a splendidly cultivated stock of the plants most required in and for the Castle. Detailed mention of these plants is not essential, but a few features must be noticed. As before mentioned, Clematis Jackmanni is grown under glass. Satisfactory Roses are Gloire de Dijon, The Bride, Niphetos, and Isabella Sprunt, the last being prized on account of the beauty of its buds. Maréchal Niel does not succeed, so is not grown. The fine old Tree Carnation, the blush Souvenir de la Malmaison, proves very useful, and none is found more valuable than Germania. The Margaret Carnations are also grown for autumn flowers. A healthy stock of Chrysanthemums was in one of the houses. The late flowering kinds are not required; but about 200 Madame C. Desgranges are grown, with from fifty to seventy other early varieties. Piercy's Seedling is valued all the season, and was in flower on the occasion of my visit.

The principal flower garden is situated in front of the houses, and although not of great extent, must be very beautiful when the beds, which are cut in the grass, are in full bloom. The situation is a picturesque one at the base of the beautifully wooded Craig Gowan. There are no walls or high hedges to cut the garden off from the surrounding grounds, and the eye travels with pleasure from the flowers to the trees, the hills, and the verdant turf. The garden is, I understand, much the same as in the time of H.R.H. the Prince Consort. Balmoral was his own property, and one can see all around it evidences of the lamented Prince's refined tastes and love of Nature in its highest aspects.

The national flower of England—the Rose—is largely grown, and is represented by various sections, both old and new being seen in the beds. From what one knows of Rose growing in the north, it was not surprising to learn that the Teas are more satisfactory than the Hybrid Perpetuals. Many of both were seen, among others being Princess Beatrice, Belle Lyonnaise, Sénateur Vaisse, W. A. Richardson, Buret, Safrano, the invaluable Isabella Sprunt, La France, Grace Darling, and Boule de Neige. There was also a bed of Old Summer Roses and Scotch Briars edged with old-fashioned Polyanthus. Between the Roses annuals are grown. Tulips were also well represented, Victoria, Duke of York, Artis, and La Candeur being among the earlier varieties. Parrot Tulips mingled with mixed late varieties were in another bed edged with Cerastium. The last is largely used, together with Arabises alpina and lucida, Silene pendula, Myosotis, Auriculas, and Violas, while herbaceous plants receive a large measure of attention. There is a dark form of Scilla italica here, and a fine display will be made in autumn by long lines of the double purple Colchicum autumnale. The old double Pæonia officinalis seems rather a favourite, if one may judge from the plants grown.

The shrubs and flowering trees about Balmoral are Lilacs, Honey-suckle, Flowering Currants, Mahonias, and Rhododendrons. Lilacs are

FIG. 116—GRAPES DUKE OF BUCCLEUCH AND MADRESFIELD COURT (page 554).

great favourites, and the common Honeysuckle is to be found almost everywhere. It covers an arched trellis over a door leading from the Castle into a series of beds on the south side; it is being trained up the lamp pillars in the entrance avenues, and to show how much this simple and fragrant flower is cared for it may be mentioned that, associated with Ivy and Cotoneaster, it climbs up the pedestals of the statues of her Majesty and H.R.H. the Prince Consort.

The flower beds at the Castle are not extensive. On the south front are mosaic beds of coloured stones, a style occasionally seen, but more common when Balmoral first became a Royal residence. On the west front facing the Royal apartments there is another series planted with herbaceous and spring bedding plants, *Viola Countess of Kintore* seemingly being a favourite at Balmoral, summer and autumn-blooming plants following in due course. There is a magnificent view from this side looking up the Dee towards Braemar, which we cannot attempt to picture.

On the north side beneath a terrace is another series of small beds occupied in summer with Pentstemons, Antirrhinums, Asters, Stocks, pegged-down Clarkias, and similar flowers. The front of the terrace is covered with Ivy, with Honeysuckle on the pillars. A row of fine Irish Yews was destroyed here by the memorable winter of 1894-5. A short walk led to a beautiful chalet, made of wood grown on the Balmoral estate, and exhibited at the Edinburgh Forestry Exhibition. It is admirably finished, the polished surfaces of the interior showing the beauty of some of our native timber. Near here is a bed of Provence Roses, and in front is a sloping bank of Mahonias. A fine view of the river Dee is obtained from this point.

The garden cottage, in which her Majesty breakfasts and conducts her correspondence, was also seen. It is a pretty little building, which, later still, will be even more attractive when the Honeysuckle, *Tropaeolum speciosum*, and the Canary Creeper climb over its walls; and an interesting feature is the number of memorial trees planted in the grounds.

It would not do to leave this Royal Highland home without ascending at least one of the hills to view Balmoral from above, and to admire the surrounding scenery. Mr. Troup, with unwearied kindness, suggested the ascent of Craig Gowan, on which is the Cairn, in commemoration of the marriage of H.R.H. the late Duke of Albany—a married life which, alas! was cut all too short. A little higher is the flagstaff on which the flag is hoisted on occasions of rejoicing, and near which the bonfires blaze. The hill is largely covered with Birch, intermingled with other trees, with an undergrowth of Juniper, Blaeberry, Whortleberry, and Heather. From the summit the view is indeed magnificent. Balmoral Castle nestles below, surrounded by its trees, its lovely grounds, and gardens. Through the valley the Dee winds along, and on both sides rise lofty mountains. I looked longingly at the Cairn on the summit of Craig Lowrigan, erected to the memory of the Prince Consort; and not to be forgotten is the beauty of the glade at the base of Craig Gowan, past the Queen's Well, with its stream of cool and limpid water. We had left to the last a look at the statues of her Majesty and Prince Albert. It was a fitting conclusion to a visit not soon to be forgotten, to look up to those representations of two noble lives, the one happily still with us, to continue long, we hope, her beneficent reign; the other cut off in early manhood, but not before the nation could realise how much it had lost by his death. And so we turned and came away. A memorable day had come and gone; a day which had brought with it much pleasure, and had given subject for deep thought.

Full of beauty as is Balmoral, magnificent as are its surroundings, we feel that it gains lustre from the thought of those whose home it was and is. We think of our Queen, to whom it is so dear, bearing so patiently, so bravely, and so well the burden of the British Crown, ever seeking to do her duty as Monarch, ever remembering the sorrows, the joys, and the triumphs of her people.

A visit to her Highland home can only intensify one's loyalty and admiration, so clearly can one see and learn that the Queen's messages to her rejoicing or sorrowing people are from the heart. Mingled with all these thoughts of her Majesty's goodness come those of him whose loss she has ever mourned. To that Prince, Balmoral, as it was and is, is due. To use her Majesty's words, it is "his own work, own building, own laying out. . . . His great taste and the impress of his dear hand have been stamped everywhere."

As Balmoral was left behind, it was with the earnest hope that our gracious Monarch may long be spared to draw strength and comfort from her beautiful Highland home and the everlasting hills, the symbols of the Eternal, which rise around.—S. ARNOTT.

Horticulture During the Queen's Reign.

SIXTY YEARS' REMINISCENCES.

WHEN I was asked to write something about the progress of horticulture during the Queen's reign, I was somewhat startled by the magnitude of the task proposed; to do it fully would have required the reading up of a great mass of literature, and would have demanded not the writing of a paper but of a volume. Although the honour which has been put upon me in asking me to write this paper is one which I duly appreciate, I must at the same time say that I have no intention of treating it as just suggested. When I come to ask myself on what grounds I have been requested to undertake this work the only answers I can find are that during those years I have been closely associated with horticulture, and that my horticultural life began some years before Her Majesty's accession to the Throne. This advantage is one that my younger brethren will not envy me, but experience is one of those good things which we old men can claim; and as I have already said in the pages of the Journal, I was in the full strength of early manhood when I saw at Milan the announcement of the death of William IV., and that his niece, our present Gracious Queen, was to succeed him.

OLD TIMES AND OLD FRIENDS.

My paper will then be rather one of personal reminiscences than of detailed historical statements. I am not one of those who are always exclaiming that the old times were better than the present, and in nothing is this less true than in horticulture. Think of the time, my friends, when there were no Japanese Chrysanthemums, no tuberous Begonias, no Hybrid Perpetual or Tea Roses worthy of mention, no *Lilium auratum*; when Orchid growers were scarce and the species cultivated few in number; and it will be then seen how very different our gardens are now to what they were in those days, and yet there is much that one can recall with pleasure, and scenes occur to one it will be impossible to equal in these days.

Especially is the recollection strong of two exhibitions which I attended in the early days of Her Majesty's reign. One of these was the great summer show in the Royal Horticultural Society's Gardens at Chiswick. This was then as much one of the days of the London season as the opening day of the Royal Academy. The whole way from the West End to Chiswick was thronged with the grand equipages of the upper ten, while the brilliancy of the toilettes of the ladies showed it to be as important to them as the day at Longchamps is to the Parisian belles. The exhibition of flowers was also in some respects remarkable. Ericas and hardwooded plants were then much more in favour than they are now, and I well remember the splendid specimens of various kinds which used to be shown by Mrs. Lawrence, who was an enthusiastic horticulturist. The day was memorable to me also, for on going across the lawn I picked up a well filled purse, and on inquiry soon found an owner, Mr. John Edwards, who was then one of the leading growers of Tulips, Auriculas, and other florist flowers in the Metropolis, which led to much pleasant intercourse with that most ardent florist. The other exhibition was a scene of a very different character, and took place at the Horns, Kennington, lately demolished; it was an exhibition of Auriculas and Polyanthus, and very keenly were the prizes (which were insignificant compared with those which are offered now) contested; but I think there was a real genuine love of the flowers manifested by all the exhibitors.

Nor in other respects were there signs wanting that there was as much enthusiasm amongst the flower loving community then as now. It is true that the extraordinary prices which have been given for Orchids in these latter days could not be paralleled then, but I remember going to Walworth to see the magnificent beds of Tulips grown by Mr. Groom, many of the bulbs in it being valued at £50 and upwards. I remember also seeing at Catleugh's shop in Chelsea, carriages standing, whose fair occupants were carrying off plants of the new *Pelargoniums* raised by Mr. Garth, who lived near Farnham, Surrey, and Mr. Foster, of Clewer Manor, for which they had paid 5 guineas a plant; and well do I also recollect the delight with which I received shortly afterwards a cutting of Garth's Joan of Arc, very brilliant in colour, but of such a form as a few years saw it quietly displaced by others. Then I call to mind beds of Persian *Ranunculus*, such as I have never since seen, so brilliant and varied were the colours, and so exquisite the form.

It may well be asked, What was the condition of our gardens at that time? The borders were filled with miscellaneous collections of plants of what people call now old-fashioned flowers. There was always plenty of colour and of perfume, although the plants were very much muddled together; while the Roses, which were scattered amongst them, were Moss and China, and others which go now under the name of summer flowering Roses; and while there are many nurseries which have risen up since those days, one must not forget that there were many in and around London, the memory of which is cherished by the few who remain of that generation. There were Rolliesson of Tooting, Glendinning of Chiswick, Jackson of Kingston, E. G. Henderson of Pine Apple Place, for whose representatives of the present day we search in vain; and there were others whose descendants still remain with us, and whose names are as household words amongst us—Veitch of Chelsea, Fraser of Lee Bridge, Low of Clapton, Cutbush of Highgate; while looking a little further afield one recollects the Rivers of Sawbridgeworth, the Pauls of Cheshunt and Waltham Cross, Turner of Slough, Smith of Worcester, Lucombe, Pince & Co. of Exeter, and Waterer of Bagshot. In all these cases the sixty years of Her Majesty's reign have witnessed a marvellous development.

With many of those good men and true whose names are first mentioned I had in those bygone days much pleasant intercourse, for I had a very omnivorous appetite, and whether the plants grown were the aristocratic Orchid or the plebeian Pansy, they never failed to interest me, and yet to many of the present generation the names of those bygone heroes of the gardening world have no meaning whatever. So it is in everything; and no matter in what a man has been interested—science, art, or literature, the past brings up the most faint shadows, which he finds it difficult to retain. It will thus be seen that my view of the state of horticulture in 1837 and thereabouts was not such as to leave too much room for boasting on the part of the present generation, while it was such as to leave room for the ample development in every department which has since taken place.

CHANGES IN GARDENS.

Having thus prepared the way to consider what those developments have been, and to what causes they are attributable, let me then take as the foundation of all, the conditions of gardens themselves now and then. I have already stated what gardens were in those days, and it is interesting to mark how fashion has moulded this as other things. Who cannot recollect the utter subversion of the gardens of old times by what is known as the bedding out system? Many an old garden had been metamorphosed by this new-fangled notion; old plants that had long by their beauty or fragrance adorned the borders were ruthlessly uprooted, and every available resource was utilised for the purpose of raising the thousands of plants which were required for this new system; and the value of a plant came to be reckoned by its capability of being used or not for this purpose. Our gardens became a mass of glaring colours in which the scarlet "Geranium," the yellow *Calceolaria*, and the blue *Lobelia* bore a conspicuous part; and long dissertations were given upon the value of some new plants which might be made available. At first these were restricted to beds; then came the rage for ribbon borders, in which long rows of red and yellow were combined with foliage plants, such as *Perilla* and *Iresine*, to be used as contrasts.

Then there came a further development of this—what was called the carpet system, in which *Alternantheras* and similar plants were used, together with various coloured stones and even glass for the walks. These beds had to be kept constantly clipped, and where the garden was any way extensive five or six men might be seen, as I have seen them, on their knees clipping away with scissors, so that you might have imagined yourself to have been in Truefitt's, while as far as beauty and fragrance were concerned you might as well have thrown a piece of Turkey carpet upon the ground. The worst feature of the whole thing was this—that it invaded our cottage gardens, and many of the old-fashioned flowers were displaced by some of these new colours, and instead of these gardens being filled with plants which could very well take care of themselves, tender things had to be grown for which some kind of protection had to be found during the winter.

There was one way, however, in which this system was found acceptable, and where it is not even now out of place—I mean in public parks and gardens. Here a mass of colour is always acceptable to the populace, and the same people do not, as in private gardens, look at it every day. Connected with this was what was called sub-tropical gardening, in which really tender plants were utilised for the same purpose; but this was almost exclusively confined to public gardens, and was extensively employed in the parks of Paris, from whence the taste came to our own country. We are a people that deal much in extremes, and when we have passed all reasonable limits there comes the revulsion of feeling and the reversion of practice.

This change of taste has completely altered the appearance of all private gardens. In places where there is room for it, various styles of gardening are still carried out; but in those of small extent, such as are by far the greater proportion of our English gardens, the herbaceous system has very nearly ousted the former glaring style; and it is curious to notice how the law of demand and supply has come into force to meet the new departure. It was not, of course, at first popular—indeed, I knew of one case where a garden had been long filled with herbaceous plants of various kinds; it passed into other hands, and these were all assiduously rooted out, to the great grief of the former occupier, who used to tell with a chuckle how this very same person after a little while was known to grope about in the rubbish heap, to try and rescue some of the plants which he had discarded, for he saw how wrong he had been, and was anxious to repair the mischief.

In consequence of this change all over the country establishments started into

existence, whose main and sometimes sole object was the cultivation of hardy herbaceous plants. The great York nursery of Messrs. Backhouse & Son had long been celebrated for these things, and I think their piece of rockwork is without exception the most perfect and successful example of the kind in the kingdom, and among my pleasant reminiscences of gardens that I have seen this holds a foremost place. Other establishments, however, soon claimed attention. Mr. Ware of Tottenham, Messrs. Paul & Son of Cheshunt, Mr. Barr of Ditton, Mr. Pritchard of Christchurch, Mr. Smith of Newry, the Guildford Hardy Plant Nursery, Mr. Wood of Kirkstall, Dicksons of Chester, Smiths of Worcester, are amongst those who have catered to the public taste in this respect. But of a truth one can hardly now go into a nursery of any extent without finding a section devoted to herbaceous plants.

FIG. 117.—PINES SMOOTH CAYENNE (page 555).

Along with the cultivation of these, hardy and half-hardy annuals have come into great request, and I notice that there is a tendency to grow the simpler formed flowers in preference to the very double ones, such as the Aster and the Marigold. Two double flowers, however, still maintain their place—the Rose and the Dahlia—though in both cases single forms have been much sought after, and were at one time very popular. There is another flower which was at one time considered the almost exclusive property of the florist, which has, however, become as popular as either of the preceding—I mean the Carnation; its delicious perfume and its brilliant colour soon made for it a place in all well-ordered gardens, and now what are called border varieties are eagerly sought after. Great impetus has been given to their culture by the establishment of the southern branch of the National Carnation and Picotee Society (although that was not the purpose for which it was established), and by the liberal action of Mr. Martin R. Smith, who is a most enthusiastic cultivator, and who distributes every year to all its members a packet of his carefully hybridised seed. I can personally testify to the excellence and variety of the flowers thus obtained.

CHANGES UNDER GLASS.

So far, then, as regards the progress of gardening in its out-of-door aspect; but what shall we say to the greenhouse and stove portions? Here the change has been as great as in the other case. Orchid houses! Why, one can recollect the time when these were few and far between; but now they are everywhere to be seen, and in the vicinity of some of our most smoky towns—notably Manchester—the plants have found many enthusiastic and successful cultivators. Out-of-door gardening is pursued in such districts under great difficulties, and hence the culture of plants under glass has seemed more congenial and more suited to the surroundings, and in places where only two or three were grown large collections are now to be found. One curious change has taken place in the cultivation of greenhouse plants—that is, the unpopularity of the Camellia: The flowers are beautiful in form and in the purity of their colouring; but many people think them too stiff, while they are quite devoid of perfume. Ladies gave them an unkind blow when they refused to use them for personal decoration, and preferred the less formal and sweetly scented Rose.

We find now in our greenhouses a more varied collection of miscellaneous plants of small size. This is occasioned by the taste for plants for house decoration, and especially for the dinner table, which shows the happy change which has taken place in dinner arrangements; so that instead of the heavy and strong smelling dishes which used to be placed on our tables, and under which they groaned, we have the utmost skill and intelligence used in decorating them with flowers in various ways. Table decoration has also gone through various changes. Many can remember when a sort of young forest of Palms, Ferns, &c., completely enveloped the guests, and tables were specially made to insert the pots in which these plants were grown. We rarely now see the huge plants which were at one time considered the best witness to the gardener's skill. One case I call to mind in which the owner had come into a large and unexpected windfall, and spent thousands of pounds in erecting a magnificent range of houses, and these were entirely filled

with large overgrown specimen Ferns and flowering plants, neither the owner or his family being able to gather any of them for fear they should spoil the symmetry of the plants.

One might say a good deal on the progress which has been made in the culture of Orchids. No such magnificent collections as those of Sir Trevor Lawrence or Baron Schröder were to be seen in the earlier days of her Majesty's reign. The fabulous prices which have been given for Orchids sufficiently attest the enthusiasm, and I may add the deep pockets, of some of our Orchid fanciers of the present day. Then, too, it has been found many of them do not require the excessive heat which they were supposed to need, and the term cool-house Orchids shows how this change has operated; and the enormously enlarged establishments of Messrs. Veitch, Sander, Bull, Williams & Son in the neighbourhood of London, and many others in the provinces, clearly indicate how great is the demand.

MARKET GARDENING

But perhaps in no department of gardening has the change been greater than that of market gardening, especially as regards the cultivation of fruits and vegetables under glass. Let anyone go through the market gardens in the neighbourhood of London, east, west, north, and south—in Essex, Middlesex, Surrey, Herts, and visit such districts as Broxbourne, Chesham, Ham, Hampton, Finchley, Swanley, Dartford, and if he has not before seen them they will indeed be a revelation. When you can go into one house and see 7 tons of the most perfectly finished Grapes, and when you know that this

house is but a sample of others in the same grounds where there are 20 acres of glass; or let him go to another from whence the proprietor has sent to Covent Garden 100 tons of Grapes in the season; or let him talk to Mr. George Monro, the eminent salesman, who will tell him that in the four days preceding Christmas, 1896, 4 tons of Grapes passed through his hands, he will be able to appreciate the wonderful progress that has been made in this department.

Connected with this one cannot but notice the remarkable development that has taken place in the culture of the Tomato. One can see acres of houses 100 to 200 feet long filled with this wholesome and agreeable vegetable or fruit (whichever we call it). I can remember the time when it was considered poisonous, and on about the same level as the berries of the Potato. We used in bygone days to grow a plant of it in our greenhouses on account of its ornamental fruit, and it then went under the name of Love Apple. At first Covent Garden used to be supplied from abroad, and even now in the early part of the season France, Spain, and the Canary Islands supply us with them; but as in the case of fruit, as soon as we can get our home-grown plants into bearing the foreigner is "obliged to take a back seat;" and as there are no Peaches, Nectarines, or Grapes equal to those in our hothouses, so all Tomatoes are inferior to those with which our market gardeners supply the London and other markets. Those amateurs who have small greenhouses have got into a way of growing Tomatoes for their own use, and they are always a welcome addition to the dinner table. As one who can remember the suspicion with which they

FIG. 118.—MELON FROGMORE ORANGE (page 555).

were once regarded I can feel the greatness of the change, and decidedly mark this as another sign of progress.

As we pass away from the culture under glass to that of hardy fruits in the open, progress seems to be equally great. If any of your readers can remember, for instance, what Strawberry culture was in the early days of her Majesty's reign, and compare it with what it is now, they will not dissent from this statement. In private gardens the Strawberry beds were made up of inferior kinds, for all the good varieties now in cultivation were unknown then. There were no Paxtons, Dr. Hoggs, Presidents, British Queens, Napiers, or, indeed, any of the fine varieties on which we now depend. The beds were oftentimes five, six, or seven years old, the runners were allowed to root themselves all over the bed, and after fruiting all the tops were cut off; but now in the best cultivated gardens they are almost regarded as annuals, the beds being renewed every year. Where this is considered too troublesome they are at most two or three years old, the shoots of the year being cut off, and consequently not allowed to root, and the plant kept close at home. But it is when we come to their cultivation for market that we see the immense change that has taken place. In Kent, around Swanley, the Crays, and other places in the neighbourhood of Southampton, and, in fact, wherever soil and situation are suitable, hundreds of acres are grown of this delicious fruit, for which there seems an ever-increasing demand. That this demand is of large dimensions may be gathered from the fact that in a good Strawberry season 11 tons have been sent up by one grower in one day from Swanley station, and that Strawberry trains are run to the great manufacturing towns of the North daily during the season.

It need hardly be said that this increased growth and large produce are accompanied by high-class cultivation, while the production of new sorts both early and late have greatly extended the duration of the season; especially in early Strawberries has this been the case, and it may well be anticipated that later varieties still further prolonging the season will reward the skill and intelligence of our hybridisers. Of course, cultivation like this is good for all concerned; it employs a large amount of labour, for machinery is unavailable here, and in the picking season the fields present an animated appearance owing to the number of women employed in gathering the fruit. We must remember that this is a culture in which we are not very likely to be interfered with by foreign growers.

BUSH AND ORCHARD FRUITS.

Again, what progress has been made in the culture of the Black Currant. It may not perhaps do to examine too closely as to what becomes of all the Black Currants that are grown; they all, however, seem to find a ready market, and are very widely cultivated. One of our eminent statesmen suggested the growth of these and other small fruits for the purpose of jam making, as a remedy for agricultural distress. Without going quite so far as that, one may say that it forms a good help to the farmer where there is easy access to railway transit. I have known, for instance, an acre to bring in £70 or £80, and this not accompanied with much expenditure of labour; and persons who formerly scoffed at the idea of growing such things are now eager to take up this industry.

The most important, however, in the hardy fruits which we cultivate are the Apple, the Plum, and the Pear; and here again we must notice the great improvement that has taken place both in the production of newer varieties and in the methods of cultivation. Although there can be no doubt that there has been less progress in these fruits than in many others, yet at the time of which I write we must remember that some of our most valued kinds were not in existence. There were no Cox's Orange Pippins and other choice Apple, and no Doyenné du Comice and other delicious Pear; still, notwithstanding the numerous varieties of these fruits which have been introduced of late years, there are many long-established favourites which have not been ousted from our gardens.

The introduction of the system of growing bush and pyramid trees, and more especially the cordon system of training introduced from

France, has to a great extent revolutionised our gardens as far as the culture of these fruits is concerned, and to see this carried out in its perfection a visit to Barham Court, near Maidstone, would show how very great is the progress made in this department of fruit culture.

It cannot, however, be said that generally speaking our orchards show any decided marks of improvement. Much attention has been drawn to this subject of late, and a visit to any of our orchards will fully confirm the statements which have been put forward. No attention was given either to the sorts cultivated or to the trees themselves. They were mostly October ripening varieties, which would not keep, consequently there was a glut about that time if the fruit crop was a large one, and then at the time when Apples would have fetched a good price we were dependant on importations from all parts of the world. There is, however, apparently a change for the better. Some of these old orchards are being remodelled, and valuable kinds are replacing the old and comparatively worthless sorts, and wherever one goes amongst the

gardens of amateurs we find that carefully selected varieties are grown and cultivated with great care.

VEGETABLES

With regard to vegetables, in some respects there has been a great improvement. The large seed establishments which have sprung up all over the country vie with one another in catering for their patrons, and supply what was in former days a difficult matter—reliable seeds; but in one respect I do not think we can congratulate ourselves. Exhibitions have encouraged people to grow large produce, and it has been the aim of seed growers to obtain such varieties the superior size of which might recommend them to the judges; but this size is obtained in many instances by deterioration in flavour. Thus we have Peas with enormous pods, but with the delicate flavour sacrificed for size; Onions, beautiful in shape and large, but with a great deal of the Spanish and Tripoli character in them, so that their pungency is reduced to a minimum; while Brussels Sprouts, whose chief merit was their delicate flavour, have been so increased in size that this has given place to coarseness. It is the same with most other vegetables, and while no doubt it evidences the great progress which has been made in the direction which hybridisers have marked out for themselves, it seems to

FIG. 119.—STRAWBERRY LA GROSSE SUCRÉE (page 556).

me to be a wrong direction. Still it is impossible to deny that on whatever side we look, whether we consider flowers, fruits, or vegetables, the last sixty years, and especially the latter half of them, have marked the most decided progress.

As to the causes which have contributed to this progress, I think we must lay down in the first place that horticulture shares in the general advance which has marked the latter half of this century; mainly owing to the increased prosperity of all classes, and their increase of wealth and consequent increased power of spending. Of course I shall

FIG. 120.—CONSERVATORY, FROGMORE (page 556).

be met by the objection that one of our chief industries, agriculture, has passed and is passing through a period of great depression; I am aware of this, but it was not the case until within the last few years, and we must bear in mind the close relationship between it and horticulture, and if there be progress in the one it must act upon the other. In fact, do not all parts of the country bear witness to the statements which have been made that market gardening is entering largely into the operations of the farmer, and that consequently improvements in horticulture must work for his good? and when the revenue of the country has exceeded £100,000,000 it will be idle to deny the fact of increased prosperity.

LOCOMOTION.

All branches of art and science have shown a progress that exceeds all that has gone before them, while in everything that tends to the material comfort of the people this gratifying change must be noticed. The large sums that are being expended in every direction have greatly helped forward the cause of horticulture. A very important factor in this development has been the increased facility of locomotion; if it had not been for this it would have been impossible that exhibitions could have been held as they have been, and that the increased demand for the productions of the horticulturists, especially in our large centres of population, could have been met. See how the Daffodils and other flowers of the Scilly Isles are brought by tons all fresh into the London markets, and to those of our great northern towns; and see, also, as I have already said, how the fruits which have been gathered in early morning are hurried off and brought temptingly fresh for their

consumers. See, too, how societies dare to invite competition from persons living a couple of hundred miles from where products have to be shown, and then think of what many others have experienced in former days when the facilities of transit were more difficult.

Many of us can remember the labour, exhaustion, and trouble in those long-past days. We still grumble that the railway companies do not treat us as well as they ought to do. There are still some annoyances connected with them, but I think it is not unlikely that these may be remedied, and further facilities given for getting the productions of the gardener to an early market. There is little doubt, I think, that the careless way in which fruit especially has been gathered and packed for market has been one great hindrance to the realisation of the profit which growers have a right to expect. I believe, however, that of late the efforts of Mr. George Monro and others, who have pointed out how this plays into the hands of the foreigner, is leading to considerable improvement, while some of the railway companies have been giving suggestions which, if carried out, must tend to the same end.

LITERATURE.

Another very potent agent in the progress that has been made in all departments of gardening may, I think, be fairly said to be the great increase in and improvement of our gardening literature. As far as I can recollect there was but one weekly journal previous to the establishment of the "Gardeners' Chronicle," under the editorship of Dr. Lindley. From the well-known position of its Editor it assumed the rôle that it has maintained all through its existence, as the exponent of the scientific aspects of gardening, and its pages have ever been open to the most distinguished botanists, both home and foreign. The *Journal of Horticulture* can now claim nearly fifty years of life, and shows no sign of decrepitude or decay. Originating in the provinces, it after a while flitted to London, where, under the wise and firm hands of its two Editors, Mr. Johnson and Dr. Hogg, it became one of the most popular of the weekly journals. The "Gardeners' Magazine," a name which I believe was originally associated with Mr. George Glenny, was for many years edited by the genial and witty Shirley Hibberd. Then came the announcement of a fourth, which took up a distinct line of its own, I mean "The Garden." It was founded by Mr. William Robinson, and from the first waged war against the extravagances to which the bedding-out system had been carried, and was the strong upholder of the cultivation of those herbaceous plants which now form so great a feature in our gardens. Its coloured plates, which are admirably executed, have no doubt been a great cause of its popularity. One, perhaps, might have thought that these papers would have been sufficient; but no, from some of the offices there have issued a sort of overflow paper, published at 1d., and thus teaching on all kinds of subjects connected with gardening every week, reaches all classes of the community, and adds, I believe, largely to the progress gardening has made.

In connection with this onward movement one may allude to the freedom with which all gardening subjects are treated in these papers. Time was, as some of us can recollect, when if a gardener was asked the cause of his success in some particular culture it was very difficult to get anything but an evasive reply from him; but it is not so now. If success attends any cultivator he is the first to make it known as widely as he can, while others are sure to notice how he succeeded. Thus the encouragement of progress becomes much more widened.

THE RESULTS OF CHEAP GLASS.

Another cause for this progress, but of a very different character, has been the taking off the duty on glass. I am quite sure that when Sir Robert Peel effected this fiscal change he had no idea of the extent to which the community would be benefited by it. The rich man has built his large conservatories and greenhouses without having the bugbear of duty to be paid before him; the market gardener has been able to cover his acres upon acres with forcing houses; the amateur hardly considers his home would be complete without a greenhouse of some kind, and if one goes through the districts round London and other large towns where artisans most congregate he is surprised at the number of small greenhouses which are attached to their humble dwellings, and in which their owners take as much pride as the Lords of Chatsworth and Trentham do in their large establishments. Tending to the same end, and probably from the same cause, has been the great reduction in the price of glass itself; it is not one-half what it used to be, and thus a man of small means has placed before him opportunities which even his richer neighbour could not enjoy in times past. In

smoky neighbourhoods this is more especially a great boon. The Rose, for instance, will not endure smoke, but I have seen many a good flower come from an artisan's greenhouse which he could not have grown in the open air, and but for these advantages those grand establishments which we see all around us for the growth of flowers and fruit would probably never have been contemplated.

THE INFLUENCE OF SOCIETIES AND EXHIBITIONS.

I know that there are many people who disparage exhibitions and the efforts that have been made to promote them, and although nothing that we have to do is free from objections, yet I am persuaded that these objections are valueless, and with regard to societies we know that in our complicated civilised system societies must be formed for all sorts of things. Foremost amongst those which have helped forward

The admirably planned and beautiful gardens of the Royal Botanical Society in Regent's Park were the scene of some of the finest exhibitions held in or about London, and no doubt greatly contributed to the increased popularity of flowers. When Paxton's gigantic palace of glass was erected on Sydenham Hill, and surrounded by beautiful gardens, another impetus was given to the promotion of horticulture; it is an ideal place for a flower show, for it affords that which our variable climate so much needs—shelter and protection from bad weather, beside other attractions to those who frequent the shows held there.

As far as the provinces are concerned, I think we may say that wherever societies exist their influence on the neighbourhood is easily seen, and yet the true lover of flowers must regret that in some of our

FIG. 121.—GARDENIAS IN ORCHID HOUSE (page 556).

this good cause is appropriately the Royal Horticultural Society. During the last sixty years it has had a curiously chequered career. We can remember the feeble gatherings both in Regent Street and Charing Cross. We can recollect how it shared in the grand plans that the late Prince Consort had formed with regard to South Kensington; we can call to mind how all these hopes were disappointed, and what a failure South Kensington was in a horticultural point of view; and we can also remember the manner in which the Committees were shunted about from one place to another, and how at last South Kensington became a byword and a reproach so far as horticulture was concerned. Still the Society held on, and then brighter days dawned, and although its location is by no means an ideal one, yet no one can doubt that the fortnightly meetings held at the Drill Hall have been of late years a very powerful incentive to everything connected with gardening.

most successful exhibitions other things which are hardly legitimate adjuncts to the flower show are brought in to make them a success. But then it has also to be remembered that but for those adjuncts many thousands of persons would not have been brought within the sphere of influence of flowers and become, as so many have, ardent cultivators. Changed habits have thus been brought about which have resulted in brighter homes and happier lives. Still, wherever these converts become true lovers of flowers extraneous attractions at shows lose to them their charms.

No one can review the effect of exhibitions on the progress of horticulture and ignore two which unquestionably had very great influence. I refer to the one held in 1866 at South Kensington, and the more frequent ones held at Manchester under the auspices of the Manchester

Botanical Society, and known as the Great Whitsuntide Show. The former was international, and exhibitors from France and Belgium alike competed. The whole was arranged under the superintendence of Mr. Gibson, the accomplished landscape gardener of Battersea Park, and a grander show it would be impossible to see. It was, however, within an ace of being a fiasco. The weather for the days on which the show was held was most unfavourable; but with daring courage the promoters determined to keep it open longer. Fine weather succeeded, crowds of visitors thronged to see it, and the whole affair was a brilliant success.

Never shall I forget the astonishment manifested by some of the foreign Rose growers when they saw the magnificent pots of Roses

FIG. 122.—PALM HOUSE (page 556).

shown by some of our great firms. It can never be too strongly insisted upon that, however much we may owe to the French for the introduction of new Roses, they are no match for us in their culture. The same astonishment was manifested at the grand Azaleas and Pelargoniums which were then so much in vogue, but are now rarely seen; and English growers were certainly encouraged by these manifestations of foreign opinion to still more persistently show their zeal in the further development of horticulture.

The Manchester exhibitions, at which I had the honour of acting as judge for many years, had a very marked effect on the progress of horticulture in the North of England. They owed their success mainly to the energy and popularity of the late Mr. Bruce Findlay. The Society was at a very low ebb when he took it up, and with the consent of his council he established these annual exhibitions. Their influence on the cultivation of Orchids was something marvellous; nowhere, and certainly not in the Metropolis, were such plants to be seen as were shown in the heated conservatory which was especially prepared for their reception. The merchant princes vied with one another in enriching their collections, and one came constantly upon groups of them discussing the merits of the various exhibits, while some of the growers for sale stood by taking down their orders. It was the only show, too, where I have

ever seen *Nepenthes* exhibited by amateurs. The show embraced all classes of plants, and unquestionably tended to a great development of horticulture.

The exhibitions at York and Shrewsbury never seemed to me to come legitimately under the designation of flower shows; they were rather galas in which many other things participated, but I suppose they must have had some influence in the progress of horticulture. I know that exhibitions in the West of England, which were always held in the autumn, such as Taunton and Weston-super-Mare, had a very appreciable effect in this direction, and, indeed, in the days when I knew them best the flower show day was considered the great event of the year, as much so as races are in other places, and in the gardens of many around these places one could see that the lessons were not thrown away, and many an enthusiastic amateur had been encouraged to improve his garden, and to incur an expenditure which without such a stimulus he would never have attempted.

In the same way the fruit exhibitions held at Edinburgh, Hereford, and other places certainly advanced the culture of our hardy fruits, and when competitors from all parts meet together they are sure to learn lessons from one another. They learn there their own defects, and if they are wise men they use the knowledge which they have thus acquired for the improvement of their culture. Why, however, it may be asked, have some of these exhibitions languished, and some passed out of existence altogether? There may be many local and personal reasons, but probably the most potent one is that of weather, a wet day oftentimes placing the balance of accounts on the wrong side. But even where this is the case the good work done by them does not die, and one can trace their effects when societies have long past into oblivion.

SPECIAL FLORAL SOCIETIES.

During the latter part of this period of sixty years we have witnessed the formation of special societies for the encouragement of special flowers, and nothing has tended to the progress of the flowers thus encouraged more than these societies. They have been formed for the Rose, Carnation and Picotee, Dahlia, Auricula, Chrysanthemum, Tulip, and Viola. Some of those have a northern and southern division, and thus all parts of the country are considered. As an example of the effect they have on culture I may simply mention the Rose. The National Rose Society was established about twenty-one years ago. At that time Rose showing had sunk as low as was possible. There were one or two shows in the Metropolis very feebly supported, and very few in the provinces; while the growers for sale were but few in number. Since then not only have there been excellent exhibitions held at the Crystal Palace, but in many places provincial shows of the Society have been held both North and South; while encouraged by its support societies have sprung up in all directions, and wherever these hold their exhibitions a great increase in Rose growing takes place. Then, again, this has led to a large increase in the number of growers for sale, and to a great extension of their operations; so beside the historic names connected with Rose culture, we meet in all parts of the country with those who have made their mark as growers of the Queen of Flowers.

More popular is perhaps the Chrysanthemum, but what would be its popularity without the exhibitions which are held in its honour? It, too, has its National Society, which holds its tournament every year at that most dingy of all places for exhibition, the Westminster Aquarium; but those provincial societies, as well as metropolitan, which have been started for the purpose of encouraging the growth of the Chrysanthemum are far more numerous than those of the Rose. And what wonderful change has taken place in the flowers themselves. I can well remember the pilgrimage one used to make every year to the late Mr. John Salter's Versailles Nursery at Hammersmith to see the new flowers which year by year he used to introduce. They were of course then the incurved, reflexed, and Pompon varieties, and when the first Japanese varieties were shown what a howl of derision they caused. No one at all imagined their capabilities, or had any conception of the size that they would attain. I am not sure that this matter of size has not been overdone, for the size of the stands in which they have been exhibited has had to be enlarged; and while they are very remarkable as a proof of the careful culture that they have received, it may well be questioned whether much has been gained in an æsthetic point of view.

I cannot leave this part of my subject without referring to the wonderful summer exhibitions which are held every year in the Temple Gardens under the auspices of the Royal Horticultural Society, when

the most marvellous products of the gardener's skill are brought together from all parts of the country, and when those interested in them have an opportunity of meeting and discussing matters connected with horticulture.

I think, too, that one may say that the establishment of the Horticultural Club has tended towards the same end. It has now been in existence since 1875, and has greatly tended towards the cultivation of kindly feelings between all classes of horticulturists. One cannot forget that it was at one of its meetings that the proposition was brought forward which broke the icy wall that had frozen the Royal Horticultural Society, and that ultimately ended in such good results. It has been made, too, the medium of returning to the foreign horticulturist that hospitality which Englishmen are sure to receive both in France and Belgium, and very warm have been the expressions made by those whom the Club has welcomed to its gatherings.

CHARITABLE AND PROVIDENT INSTITUTIONS.

The last sixty years have also witnessed the wonderful progress made by the Royal Gardeners' Benevolent Institution, and by its younger sister the Royal Gardeners' Orphan Fund. These must both tend to the encouragement of gardeners, and so to that of the craft. I hear it sometimes said that gardeners ought to support the former more than they do, and perhaps they ought; but then it must be remembered that a gardener's situation is not a permanent one, and so he may be unable to continue the subscription, which he may be sorry to give up. The Royal Gardeners' Orphan Fund was instituted, as we all know, in honour of Her Majesty's Jubilee ten years ago, and its progress, I think, has surprised even those who watched over its cradle. I remember talking over with some of its promoters as to what form it should take, and it was strongly urged that that which many advocated should be avoided; and I am sure the Society has no cause to regret that this advice was adopted, and it is a great consolation to a gardener that should his life not be spared his children may not want a helping hand to bring them forward. There are other institutions of a most commendable kind, such as the United Horticultural Provident Institution, which have excellent objects in view; but the two first named are the principal charitable ones which appeal to the sympathies and kindly actions of all horticulturists.

ENTERPRISE IN COLLECTING PLANTS.

There are unquestionably two sources from whence the great advance in gardening has sprung, and which cannot be left out of consideration here. I mean the efforts of foreign collectors to introduce new species into our gardens, and the efforts of the hybridiser. With regard to the first of these there are two elements in it—the enterprise of those who send out these collectors, and the efforts of the men themselves, while there are others as amateurs who have gone out on their own initiative, and all combined have added materially to the enrichment of our gardens. Hardly any part of the world has escaped the plant hunter. He has gone to the tropical regions of Asia and Africa and America, he has swept over the cold regions of the North, has climbed the alpine heights of Central Europe, of the Himalayas, has brought home the treasures of that paradise of bulbs, South Africa; he has visited the Southern seas and the Australian colonies, and the gardens of all, high and low, rich and poor, have benefited by his energy and research.

Probably the richest field has been what sixty years ago was an almost unknown region—the islands of Japan. Botanists like Thunberg had visited it, and described its productions; pictures drawn by Japanese artists of their indigenous flowers had reached us. Most people considered these were exaggerations, while others thought they were such clever imitations of Nature that they must have had the flowers before them when they made the drawings. When, then, the old exclusive system of Government was broken up, and Japan no longer remained a sealed book, it was no wonder that some of our enterprising firms at home turned their attention to the far East, and sent out those who might be worthy representatives, and on whose skill, intelligence, and energy they might depend.

THE FIRST ENGLISH FLOWERED LILIUM AURATUM.

Mr. John Gould Veitch, of the great Chelsea firm, and Mr. Robert Fortune, in connection with the late Mr. John Standish, did their best to explore the country, and what riches they found to reward their labours. Well do I remember the feverish anxiety with which the opening of the Royal Horticultural Society's Gardens at Kensington in 1861 was looked forward to. Would such and such plants be in flower? and would they be fit for exhibition on the opening day? and well do I

recollect the delight with which my old friend John Standish placed upon the table a plant of *Lilium auratum*—the first that had ever been seen in flower in England—with just one bloom open, a plant which Mr. Rucker of Wandsworth carried off in great triumph, after having paid fifteen guineas for it. This was the first-fruits of a mighty harvest. Millions of bulbs we may say of this Lily have since been imported, and many of them have been obtainable at the cost of a few pence. But with all this the progress of horticulture has not conquered the difficulty of the culture of this Lily; indeed, it has almost come to be considered as an annual. The (to my mind) far more beautiful *Lilium speciosum* was introduced a few years before this, but its importation in large quantities bringing it within the reach of all must be placed at this period.

AMPELOPSIS VEITCHI.

It is not in Lilies alone that these explorers added to the treasures of our garden; there were flowering shrubs and trees of ornamental foliage, such as the Maples and Clematis, and also herbaceous plants, which have found their way in the gardens wherever attention is given to the cultivation of what will add to their ornamentation. Probably the most popular and useful plant which we owe to Mr. Veitch's energy is *Ampelopsis Veitchi*, and when I look upon my church, the south side of which covered by its growth, and which is one blaze of scarlet in autumn, I cannot but feel how great is the debt we owe to its introducer. We cannot forget the services of collectors in the enrichment of our gardens when we see what a change has been wrought by Mr. Fortune's introduction of the little Chusan Daisy, as it was called, the forerunner of our Pompon Chrysanthemum; or the "Ragged Jacks" of the Japanese Chrysanthemum, which was so sneered at at first, but which has shown such marvellous development that missionaries and military men have in no small degree added to the beauty of our gardens. Such men as Mr. Parish in Burma and Mr. Ellis in Madagascar have shown that, in addition to their own special work, they were able to help forward the introduction of beautiful and rare Orchids; while quite

FIG. 123.—ARCHED PEAR TRELLISES (page 558).

lately Mr. Henry of N. China has discovered and introduced into our gardens one of the most beautiful of Lilies, *Lilium Henri*.

AFRICAN AND AMERICAN PLANTS.

Then again what marvellous and beautiful additions have been made from what I have called that paradise of bulbous plants, South Africa, amongst which one must include that loveliest of terrestrial Orchids *Disa grandiflora*. This was known before the period to which I allude, but no one had mastered its cultivation until the late Mr. Charles Leach took it in hand and exhibited it in full bloom at the opening show of South

Kensington in 1861. I asked old Donald Beaton on the opening day, "Have you seen Standish's new Lily?" "Yes," he said; "but I have seen something much better worth looking at," and he brought me before Mr. Leach's collection of Disas. "I have long wished," he said, "to see what I felt must be a most lovely thing, and now my wish is gratified." The fact which rivetted Mr. Leach's attention was that when the plant had done flowering there appeared a shoot at the base, and instead of drying the plant off, as cultivators had previously done, he repotted it at once, and so succeeded in overcoming the difficulties which had been

FIG. 124.—MR. OWEN THOMAS (page 562).

connected with it. He did not keep this information to himself, but let all the world know how he had succeeded.

Passing away to the New World, the districts of Central America have been explored, and we should almost have said denuded, of its lovely Orchids, many of which being produced in some of the hottest regions of the world has made their importation to Europe so difficult. I remember once visiting a celebrated establishment in the Metropolis where new and rare plants were the special object of the owner, and while I was there some boxes of Orchids arrived from Central America, but the greater portion of them were a pulpy mass, yet hundreds of pounds had been expended in the venture. This is the home of those beautiful *Laelias* and *Cattleyas*, while *Odontoglossums* and *Dendrobiums* have been introduced from the same regions. In the "Orchid Hunters' Adventures" Mr. Millican shows us something of the dangers and difficulties to which collectors are exposed in order to enrich our plant houses. Many of these plants, such as *Cattleyas* and *Laelias*, grow high up on the trees, and it has been found necessary to cut down the trees in order to obtain them.

North America, too, has enriched our gardens, but the greater portion of the plants introduced from there are hardy; the rich Lilies, the terrestrial Orchids, and various other bulbs and flowering plants have been by the zeal and perseverance of our collectors added to our stores. Take for instance a very common plant, the Columbine; the old flowers that used to be the denizens of our gardens were pretty enough, but since the introduction of *Aquilegia chrysantha*, *Skinneri*, and others, what wonderful progress has been made in them, their graceful forms and infinite variety of colour making them most attractive. Nor must we forget the fine Conifers which have been introduced to us from the

same region; although I am afraid that the *Wellingtonia* and *Araucarias* will never add much to the beauty of our English landscapes.

ROCK AND ALPINE PLANTS.

One feature connected with the progress of horticulture and the improvement of our gardens has been the re-introduction and better arrangement of rock gardens. These are no longer filled with unsuitable plants, but all the mountainous districts of the world have been ransacked to fill them, and plants which we were formerly led to consider could only be seen in high mountain latitudes now flourish in all parts of the country. Take for example the *Edelweiss*. Every traveller who had anything to do with a garden vainly essayed in many instances to bring home a plant; but now, as it freely produces seed with us, plants are every year raised in considerable numbers, and although there may not be sentiment connected with it as there is with a plant gathered in the high Alps, yet we can enjoy it if we only put sentiment on one side.

The environments of plants have been studied in their native habitats, and the knowledge thus acquired has been made use of in overcoming the difficulties of culture; more especially has this been the case with regard to plants that dislike lime. We have long known that it is a hopeless thing to attempt to grow the *Rhododendrons*, *Kalmias*, and what are ordinarily called American plants, anywhere on the chalk formation, but there are lowly plants which equally refuse to grow in such districts or in such soils, and many a failure has had to be noticed which after a long while we have found out to be due to this cause; and it is impossible to ascertain this without experience, for there are some plants, of the same family even, which refuse to grow in calcareous soil, although other closely allied species are quite at home in it; thus in the lowly tribe of *Saxifragas*, while most of them will grow almost anywhere, there are some which, like *S. oppositifolia*, drag on a miserable existence in it. Many growers for sale of these plants make a point of noting in their catalogues the peculiar conditions required for their successful growth—and thus it is from the Himalayas, the mountains of Asia Minor, the Carpathians, Dolomites Appenines, Alps and Pyrenees, our rockeries have been enriched with the most lovely gems.

There are ever still some of the alpine plants which we cannot make amenable to our wishes; thus, for instance, that little gem, the *Eritrichium nanum*, which forms a carpet of the most lovely blue in some places of the Engadine, will not survive in our lower latitudes; but with all, if we recollect what rockeries used to be, and what horrors some of them were, it is refreshing to note the wondrous change and development which has taken place. No one years ago would have attempted to do what a friend of mine did after visiting the Pyrenees. He had seen the beautiful *Ramondia pyrenaica*, and with some difficulty obtained plants of it. When he came home he got blocks of the red sandstone from fifty miles away, placed them in his rock garden, bored holes in the face of them, in which he placed his plants, and grew them to a perfection that I have never seen elsewhere. How much we owe to such enthusiasts as these! how much they have tended to the progress of horticulture and how fervently it is to be hoped that they will leave others behind who will show the same zeal and love as their predecessors have done.

ACHIEVEMENTS IN HYBRIDISATION.

But if we owe much to the zealous collector and the careful cultivator of introduced plants, what is to be said about the hybridiser? This is a subject which appals one by its magnitude, for there is not a department of horticulture which has been left untouched by him. Time was when it was considered that there were certain classes of plants to be kept sacred from his innovations, and botanists in many instances scoffed at him; but he very soon turned the tables on them when he began to interfere in what had been considered the sacred territory of the Orchid. In some of the classes of this flower, however, he has been most successful, and now no department seems to be free from his audacious attempts. And here let us remember that some of our foreign horticulturists quite equal, if they do not excel, us. For a long time many of the French growers especially have been noted for their success as hybridisers, amongst whom I think the palm must be given to M. Lemoine of Nancy, who in so many classes of garden flowers has given us such happy results. They have set us an example which many of our home growers have not been slow to follow.

Take, for example, the Rose. At one time they had almost the field to themselves, and even now they almost hold it with regard to the Tea Rose; but the late Mr. Henry Bennett, when he took the matter up,

soon ran rapidly ahead. I do not believe that the older varieties of French Roses are the result of artificial hybridising, but the produce of seed which has been promiscuously gathered from flowers which had probably been fertilised by insect agency, and of later years they have given us but few flowers, except in the Tea class, which are of value. Mr. Bennett, however, introduced the system of systematic cross fertilisation, which, before his time, had been but partially exercised by some of our home growers. He made some mistakes, as was inevitable; but he has given us some grand flowers, of which Her Majesty and Mrs. John Laing stand out pre-eminent. Messrs. Alexander Dickson & Sons of Newtownards followed his example, and to them we are indebted for some beautiful flowers. In this connection, too, the labours of William and George Paul should not be forgotten.

Then, again, look at Begonias. I recollect many years ago an eminent grower saying to me, "What flowers shall we attempt to improve next?" and when I hesitated as to a reply he said, "I shall try the Begonia," and how well the speaker, Mr. John Laing, has succeeded we very well know. He and Mr. Henry Cannell run neck and neck, and now they and others have brought the flower to such a pitch that amateurs are beginning to say, "Too big." Thus it now hardly ever occurs to anyone to grow the named varieties; but, as in the case of the Cineraria, Calceolaria, Gloxinia, Primula, and other flowers they are contented to sow the seed each year. Not less noticeable is the quick and almost wonderful advance that has been made in the brilliant Hippeastrums and the chastely pencilled Streptocarpus, as was recently exhibited by Messrs. Veitch at the Temple Show.

Take, again, the Gladiolus. Many years ago we were satisfied with a spike of four or five flowers expanded at the same time, but thanks to the energy and intelligence of Mons. Souchet in France, and of Messrs. Kelway and Burrell at home, we have flowers which have sometimes from eighteen to twenty expanded blooms open at the same time, and these blooms three times the size of those we used to grow. I have only used these as samples of the progress which has been made, but the same results have attended the exertions of hybridisers in other directions. Thus the pretty and fragrant Sweet Pea has fallen under the magic wand of Mr. Eckford, and colours hitherto undreamt of have appeared amongst them. Then, again, the Narcissus; one cannot tell how many of the varieties now in cultivation are the results of cross fertilisation, but one does know that both abroad and at home such men as De Graaf and Engleheart have been busily at work, and have obtained some remarkable results. Look also at what has been accomplished with Cyclamen persicum, contrasting the species as figured in 1837 with one of Messrs. Sutton & Sons' giants in 1897 (fig. 128, page 578). This may be taken as typical of the advance in other plants, and it would be difficult to name any flower which has not more or less been improved during the last sixty years.

Then as plants of more stately habit we have the magnificent Clematises—veritable triumphs of the hybridiser's art, and well is remembered the admiration incited by the now familiar C. Jackmanni when it first came upon the scene about thirty-five years ago, while other beauties have been constantly following in its train. Nor is it easy to forget the effect produced when Mr. C. F. Bause raised the first seedling Coleuses at Chiswick—varieties which no one had anticipated; while later, he may be said to have revolutionised the Dracenas, and brought forth a new and brilliant contingent of beautiful foliaged plants for our stoves and homes.

Fruits have also, both here and in America, been brought under the power of the hybridiser. At home Mr. Rivers of Sawbridgeworth has been for many years engaged in the improvement of some of our most esteemed fruits; and there is no doubt that great results have been achieved, both in the earlier ripening of some of them and their more

prolific character. In Nectarines and Peaches and Plums especially, valuable additions have been obtained. From America we have also received excellent varieties, both as regards quality and free bearing. It is natural to expect that a fruit so luscious and generally valued as the Grape should have tempted the hybridiser, and yet we cannot say that striking progress has been made. Many varieties have been brought forward, and may have obtained notoriety for a time, but it has been only temporary, and in course of time the older sorts have re-asserted themselves; yet such as the Duke of Buccleuch, Madresfield Court, and Mrs. Pince seem to have become established.

WORTHIES OF THE PAST.

Having rapidly glanced at the progress of horticulture during the last sixty years, I come to ask, Who are the men to whom we are most indebted for this remarkable development? I think it will be better in treating of this portion of my subject to avoid all reference to those living amongst us. Either from want of memory or want of knowing I might perhaps omit some who might consider that they were entitled to be included. I know that some of the names that I may bring forward convey no meaning to the present generation, for it is true here, as in other cases, that men are soon forgotten. As the wave which comes thundering upon the beach recedes and another takes its place, so it is with us; we may have thought we fill an important place, but those who succeed us are probably ignorant of our very existence. It is so in all stations of life. Go to a place where you lived forty or fifty years ago, and where you were tolerably well before the public, and you will be humiliated to find how you are entirely forgotten; and this must be my excuse if some of the names which I mention may lead my readers to ask, "Who is he?"

ROBERT MARNOCK AND JOHN GIBSON.

The task is a somewhat difficult one because of the many branches connected with horticulture in which men have been conspicuous, and have helped forward its development in one or other of its branches. Take, for example, the matter of landscape gardening. How much we are indebted to that kindly and intelligent man, Robert Marnock! and yet how few there are who, when they go through the Botanic Gardens in Regent's Park, ever think of asking who laid those gardens out!

FIG. 125.—ENTRANCE TO OSBORNE HOUSE (page 564).

Then, again, when what is called the subtropical garden came into vogue, how much did John Gibson of Battersea Park show what could be done in this direction! We were happily delivered from the system of which Mr. Nesfield was the originator, and Mr. Marnock has left those behind him who are working on the same line as their master.

JAMES VEITCH.

I had more than once the pleasure of meeting one whose open-handedness and enterprise led to the building of what we may, I think, consider the foremost horticultural establishment in the kingdom—Mr.

James Veitch of Chelsea, who has left his mark not only on the establishment which bears his name, but on horticulture generally. He was a stalwart friend of the Horticultural Society, and in many of its trying experiences gave it the benefit of his sound advice and generosity.

DR LINDLEY.

I never saw much of one whose name is frequently mentioned, as it well deserves to be, although he was more of a botanist than a horticulturist—I mean Dr. Lindley. Indeed, there were some forms of horticulture that he could hardly avoid treating with contempt. He

see his name attached to a plant, can tell you who Robert Fortune was. His laborious travels told upon his health, and he passed away at a comparatively early age.

JOHN STANDISH AND ANTHONY WATERER.

From those apparently unpromising districts of Surrey where it would be difficult to grow anything in the shape of cereals, two names come before me now of men who in one department helped forward that branch of horticulture in which they were interested—namely, John Standish and Anthony Waterer. The former had grand ideas, which he was never able to realise, but first at Bagshot and afterwards at Ascot his energy enabled him to achieve much. If he had had the wealth of Monte Christo or the Treasure Island he would have found means for employing it in his favourite pursuit. I remember once how full he was of a plan of a Strawberry express from Ascot to London, and how he was to outdo the railway and every other method of conveyance by its means. He was strong on the matter of hybridising, and was the means of introducing many good things; but more especially does horticulture owe him much through his employment of Mr. Robert Fortune in Japan and China, and for the many fine things introduced by him.

Mr. Anthony Waterer, who has but lately passed away from amongst us, did more, I think, to encourage the growth of Rhododendrons and what are ordinarily called American plants than anyone that I can recollect. He was not satisfied with making his display at Knap Hill, and drawing thither all lovers of these beautiful shrubs, but every spring large bushes of them

FIG. 126.—OSBORNE HOUSE (page 564).

was a masterful man, and, like most men of that stamp, very much liked to have his own way. He did not care about the florists, he used to scoff at what he considered their obtrusive operation with flowers, but though he used to come down sledge hammer-like, one could see that his heart was in what he undertook; and when the offensive and personal character of Glenny's "Gardeners' Gazette" roused the ire of horticulturists, his bold and scientific treatment, as the first Editor of the "Gardener's Chronicle," made its mark upon the gardening literature, and raised its tone. His name is connected with the admirable library which he had gathered together, and which is now housed in the Council room of the Society which he loved so well.

DR. HOGG.

But there is another doctor who has been endeared to many about whose recent departure from amongst us so much has been said, and of whom, after six-and-thirty years' intercourse with him, I could say much more; but I must leave all personal considerations on one side and speak of him in this connection as a public man, for such had Dr. Hogg been for a great many years, and his influence on the progress of horticulture has been of a very marked character. He was keenly alive to its interests in all departments, though of course it was in Pomology that he was such a tower of strength, and his *magnum opus*, "The Fruit Manual," is his best monument. With what scrupulous care and impartiality he threw together his information on this difficult subject has been recognised both at home and abroad. He was ever ready to lay his stores of knowledge before any who sought his opinions, and they were always treated with such courtesy and geniality that if they were enthusiasts before he made them doubly so, and many an one has dated a fresh departure in their horticultural life from intercourse with him.

ROBERT FORTUNE.

I several times met that most earnest and indefatigable collector, Robert Fortune. He was a pleasant and agreeable man, and clear and lucid writer; it would be impossible to say what department had not been enriched by his labours. He had a grand field, at that time almost unknown to Europeans, and he collected a great number of excellent things—Conifers, shrubs, Lilies and herbaceous plants—which were either brought or sent home by him; but there are few who, when they

were taken up, and a display made at the Botanic Gardens or some one of the London squares. I have seen them in grand order at the great Whitsuntide shows at Manchester, and many both in Lancashire and Cheshire have been thereby encouraged to grow them. Mr. Waterer was what is ordinarily called a rough diamond, but under that somewhat rugged manner those who knew him could trace a kindly heart and an anxious desire to help forward all those who were interested in the department he especially affected. The soil of Surrey is peculiarly adapted to the culture of his favourite plants, but the climate is not equally so. They are subject to spring frosts, and to see them in perfection one has to go to South Wales, and see in the gardens of Lord Swansea and Sir John Llewelyn, or to the South-West of Scotland at Lord Stairs, at Inch Castle, not only what the hybrids raised at Bagshot could do, but also to see the Sikkim Rhododendrons almost as forest trees.

THE REV. M. J. BERKELEY.

The Rev. M. J. Berkeley has so recently passed away that a good many must well recollect the genial and happy features that marked the first fungologist of our times, and who rendered valuable services to horticulture amongst those various diseases which as "Old Smellfungus" (as he was pleasantly called among those who knew him, a name which he never resented) he was continually searching out and telling people how to combat.

SHIRLEY HIBBERD.

There are few men who have been more missed, not only in the metropolis but in various parts of the country, or one who laboured harder in promoting horticulture, than the late kind, genial, and witty Shirley Hibberd. Most of us can recall many a pleasant hour spent with him, when one was always sure to learn something. He was an enthusiast with a keen eye to all that was beautiful in Nature, and both by his writings, which were numerous, and by his practical experience stimulated many who might otherwise have been inclined to lag in whatever branch they had taken up. Whatever was the subject in which he was interested he carried it out thoroughly. Some I know would say too far, but it is surely better to err on that side than on that of indifference.

THOMAS RIVERS.

All who have engaged in either the culture of Roses or that of fruit will, I think, be ready to acknowledge the debt of gratitude they owe to

that grand old gardener Thomas Rivers, who at a time when comparatively little had been written on either subject, laid us under an obligation to him for his "Rose Amateur's Guide" and "Miniature Fruit Garden." Under him, too, Sawbridgeworth became classic ground. Visitors came to it from all parts of the world to see the experiments that were continually being carried out there, especially in fruit growing, and none ever left it without being impressed with the mass of intelligence, shrewdness, and good feeling of the proprietor. It may be that some of his theories have not held their ground, but few will deny that he greatly helped forward the progress of fruit culture. From his journeys to France and Belgium he brought home much solid experience and knowledge, and the various systems of training adopted abroad owe to him, perhaps more than anyone else, their popularity in this country. In Rose culture he was eclipsed perhaps by others, but in fruit culture by none.

JOHN PEARSON.

There was one other fruit grower whom we may perhaps place next to him for the services rendered to that important branch of gardening—Mr. J. R. Pearson of Chilwell, Notts. I can bring to memory a very pleasant and profitable day spent there many years ago, and although I was not a fruit grower, I experienced as much courtesy and kindness as if I had come there with an order for 1000 fruit trees. At that time he was especially taken up with Grape culture and the production of new varieties, but in all departments a high state of proficiency was preserved, and it is pleasant to note that both at Sawbridgeworth and Chilwell the old traditions are faithfully observed and carried out.

CHARLES TURNER

It could not have been much less than fifty years ago since I paid a visit to the late Mr. Charles Turner, who was then residing at Chalvey, near Slough, then with a small garden and a few frames, but who some years afterwards migrated to the Royal Nurseries, Slough, and I think to him more than to anyone else must be ascribed the merit of keeping alive the love for florist flowers in the neighbourhood of the metropolis. Tulips, Auriculas, Pinks, Dahlias, Carnations, Picotees, and Roses were grown with such success at Slough, that many were encouraged in their culture. He had at one time a grand collection of Tulips, but nothing seemed able to induce people to grow them in the South, and I remember Mr. Turner when he gave them up saying it would pay him better to grow Lettuces. Here, again, one is thankful to be able to say the fame and reputation of the establishment are well maintained.

JOHN KEYNES.

I wonder how many recollect old John Keynes of Salisbury, and yet few men did more to advance the culture of the Dahlia. He and Charles Turner used to run a neck-and-neck race both in exhibitions and production of new varieties; not that his attention was confined to these, but they formed the groundwork of the establishment which he built up. He did not commence life as a gardener, and it was his love for flowers that led him to change his vocation. He first began as a Pink grower, and was fond of telling a story of those early days, and how, when driving off to a show some miles distant from Salisbury, the trap he was in came to grief, and he and another Pink grower who was going with him were thrown out. "I escaped," he used to say, "without injury, but my friend's leg was broken." Such, however, was his enthusiasm, that he obtained another trap, and in spite of the broken leg they drove off to the place of exhibition, but (then he used to add with a quiet twinkle of his eye) "the leg was a wooden one."

SIR JOSEPH PAXTON.

Amongst those names which should ever stand forth as connected with horticulture in the Victorian era is that of Sir Joseph Paxton, though it will probably be mainly in the grand exhibition buildings of 1851 and with the Crystal Palace, its immediate successor, that his name will be mostly remembered. The accomplished gardener of Chatsworth,

whose genius elaborated the design of the grand building in Hyde Park, had a great influence on horticulture. The world saw that there were some gardeners that did not only wield the spade and the hoe, but also the pen and the pencil, and so was inclined to estimate at a higher figure those who led the van in the various departments of gardening. The profession felt honoured by the distinctions conferred on its most illustrious member, and were no longer inclined to use the expression, *Only a gardener*; and there can be little doubt that the establishment at the Crystal Palace has led to the great encouragement of high-class gardening.

WILLIAM THOMSON.

The names of two brothers—one of whom still remains with us—namely, David and William Thomson, both deserve notice; but following the rule I have laid down I say nothing of the former. Probably there is no person who gave a greater stimulus to Grape-growing for profit than the latter. At Galashiels he led the van in this branch of gardening, and I think it is not too much to say that the vast establishments which we now see in the neighbourhood of London owe their development to the example set there, and I believe that this is recognised by many of the owners of these places, some of whom, at least, hail from the other side of the Tweed.

THOMAS MOORE.

So years ago there was no more familiar name in the gardening world than that of Thomas Moore, the curator of the Apothecary's Garden at Chelsea. He was a very glutton for work, and as is usual in such cases, people never hesitated about laying it upon his shoulders. He was a prolific writer, and as his knowledge was extensive, he helped forward many in the pursuit they loved, and wherever a committee was to be formed or society started, and the question came, Whom shall we ask to be secretary? the invariable reply was, Thomas Moore. At one time associated with Dr. Lindley in the "Gardener's Chronicle," and known to a wide circle, and he continued his activity until the disease which finally carried him off, made such inroads upon his health that work was impossible.

JOHN DOMINY.

I have mentioned the hybridisation of Orchids, and I think that it ought not to be forgotten that the leader in this work to whose intelligence and skill we owe so much, was John Dominy, an employé in the great Chelsea firm of Veitch & Sons. A quiet, modest, and unassuming man, he was never willing to put himself forward, one who would do anything rather than say a few words. He not only ventured

FIG. 127.—OSBORNE HOUSE TERRACE (page 564).

on ground hitherto untrodden, but led the way in which many others have since followed, and he showed conclusively how flowers of a complicated structure are not beyond the reach of the hybridiser. By his success he encouraged others to persevere in the same line, and whenever I see a hybrid Orchid, the quiet and modest bearing of John Dominy are present with me.

B. S. WILLIAMS.

While I am mentioning Orchids one must not forget the late Mr. B. S. Williams of Holloway. Greatly devoted to this class of plants, he did what he could to popularise them in various parts of the country.

The frequenters of the great Whitsuntide show at Manchester will not readily forget his portly form and beaming countenance in that great assembly, and much of the progress of Orchid growing in that neighbourhood is due to him. Every year he used to bring down collections of the newest and best kinds, and growers had thus the opportunity of seeing their value close at home.

BRUCE FINDLAY.

As I have frequently mentioned this exhibition, I think it would be ungracious not to say something of Mr. Bruce Findlay, to whom, as I have said, its success was mainly due. He was a first-rate organiser, cool and calm in all that he did. The eccentricities of exhibitors, their fussiness, and often their unreasonable complaints, never disturbed his equanimity. I have seen people come up to him swelling with indignation, but a few words from him would set the matter right, and they went away convinced that no fault lay with the manager of the

gardening was most picturesque, and Mr. Ingram made the most of its capabilities, and when anyone contemplated carrying out spring bedding they always wanted to know what Ingram had done at Belvoir. It is almost impossible to speak too highly of the man himself; he was in truth one of Nature's gentlemen, and worthy to be placed alongside the most distinguished names in horticulture.

OTHER GOOD MEN.

There are two or three names of other good men who as hybridisers have advanced the cause of horticulture. While Mr. Pearson of Chilwell was adding to our lists of Zonal Pelargoniums there was a quiet man in London who was doing the same, the late Dr. Denny. So also was Mr. Ingram, for a long time her Majesty's gardener at Frogmore; he raised some varieties which are still in use, and to him we owe also some fine varieties of Strawberries. Nor, again, must we forget Mr. Gilbert of Burleigh, a raiser of several vegetables which are still in cultivation.

FIG. 128.—CYCLAMEN PERSICUM—1837.

CYCLAMEN PERSICUM SUTTON'S GIANT—1897 (page 575).

exhibition. The esteem in which he was held was evidenced by the deep sorrow felt at his death, and also by the testimonials given to him.

REV. JOSHUA DIX.

Visitors to the Council room of the Royal Horticultural Society may have noticed amongst the few portraits that of a quiet, placid looking clergyman, of whom a great many of the present generation have never heard, and yet his influence on horticulture was no slight one. In the early days of the ill-fated South Kensington, the Rev. Joshua Dix took an active part in promoting its welfare, and his quiet and unobtrusive manner ever gained him the attention of those he wished to influence, yet, as I have said, few remember even his name.

WILLIAM INGRAM.

In the days when spring bedding was much more in vogue than it is at present no one tended more to its development than William Ingram of Belvoir. That princely home of the Dukes of Rutland afforded ample scope for the display of his genius, and amongst especial treats which many a horticulturist enjoyed was a visit to this grand residence. Its magnificent trees and grassy slopes and commanding position made it a special spot for a pilgrimage. The place selected for the spring

REFLECTIONS.

I have thus endeavoured, I know but very imperfectly, to set down some facts tending to show that horticulture has shared in the wonderful progress which the sixty years of Her Majesty's reign have borne witness to. I have shown where the advance has been, the causes which have led to it, and the men by whom it has been carried out. Unhappily, the terrible depression from which agriculture has suffered has had its bearing upon the kindred profession of horticulture; but just as the Chancellor of the Exchequer has shown that neither the competition of foreign nations nor the blindness of our own people has hindered the development of the resources of the empire, so the same circumstances have not hindered the advancement of horticulture. What this progress might have been but for the disturbing elements to which I have alluded it is impossible for me to say; and as I look back upon my long apprenticeship to this science I must record the pleasure and happiness it has given me, and how many true and kind friends it has made for me; and as I think upon the younger men who are now engaged in it I can only hope that, bringing to it a loving feeling, they may be able also at the end of sixty years to record the same feelings of thankfulness that I am now able to do.—D., Deal.
